# **1. Introduction**

The Integrated Water Flow Model (IWFM) is a fully documented FORTRAN-based computerized mathematical model that simulates ground water flow, stream flow, and surface water – ground water interactions. IWFM was developed by staff at the California Department of Water Resources (DWR). IWFM is GNU licensed software, and all the source codes, executables, documentation, and training material, are freely available on DWR’s website. The model was first released to the public by DWR in 2003 as IGSM2 (Integrated Groundwater-Surface water Model version 2). IGSM2 itself was a completely revised version, in theory and code, of IGSM which was originally developed in 1990 for a group of State and local agencies in California (including DWR). This document reviews in detail the principles, theories, and assumptions that form the engine for IWFM.

## **1.1. Overview of IWFM Theoretical Documentation**

Chapter 1 of this document reviews the history of IWFM, and briefly explains the model features.

In Chapter 2, the conservation equations that are used to model the hydrological processes simulated in IWFM are detailed. The hydrological processes that are simulated in IWFM are the groundwater heads in a multi-layer aquifer system, stream flows, lakes (open water bodies), direct runoff of precipitation, return flow from irrigation water, infiltration, evapotranspiration, vertical moisture movement in the root zone and the

unsaturated zone that lies between the root zone and the saturated groundwater system. The interaction between the aquifer, streams and lakes as well as land subsidence, tile drainage, subsurface irrigation and the runoff from small watersheds adjacent to model domain are also modeled by IWFM. Mathematical models that are used for each of the above processes are developed and discussed thoroughly in this chapter.

Chapter 3 details the numerical methods used in IWFM to solve the differential equations that model the hydrological processes listed in Chapter 2 and the interactions between them. The methods used to store large matrices in a computer-memory efficient way is also described in this chapter. Finally, techniques that are used to calculate parameter values at finite element nodes based on values measured only at a few locations are discussed.

In Chapter 4, the demand, simulation of water supply and water allocation process are discussed. This chapter is integral to understanding one of the main objectives of the model; simulating water supply for the purpose of meeting a demand. Explanation of the land use approach in the model, and allocation of water based on land use needs are included in this chapter. The methods used to adjust water supply in order to meet the demand are also discussed.

## **1.2. History of IWFM Development**

IWFM was first released by DWR to the public as IGSM2 in December 2002. In September 2005 the name IGSM2 was changed to IWFM to avoid confusion with another model IGSM (same acronym but a different code and theoretical basis); versions

of IGSM are still in use today. Additional details can be found in Appendix B. IGSM2 Version 1.0 was made available to the public in December 2002. IGSM2 Version 1.01 which included minor corrections was released shortly after, in January 2003. IGSM2 Version 2.0 and Version 2.01 were released in December 2003 and March 2004, respectively. Version 2.0 incorporated more robust solution techniques, new features and improved output files, whereas Version 2.01 included minor corrections. Later, IGSM2 Version 2.2 which included a new zone budgeting post-processor was released in February 2005. IGSM2 Version 2.3, which was renamed as IWFEM Version 2.3, was released in September 2005 and included minor additional features and modified output files compared to IGSM2 Version 2.2. IWFEM Version 2.4 that included a modified methodology for routing soil moisture in the root zone was released in May 2006. IWFEM Version 3.0 mostly included structural changes in the source code that was the start of an effort to move to an object-oriented programming paradigm. Time-tracking simulations, option to print groundwater heads and subsidence values in a Tecplot-compliant format to create animations, and new features in the simulation of the root zone soil moisture were part of this version. IWFEM Version 3.0 was released in February 2007. Version 3.02, which was released to the public in April 2010, included a new solver that uses the generalized preconditioned conjugate gradient method for shorter run-times, modifications to the source code to increase run-time efficiencies, and bug fixes.

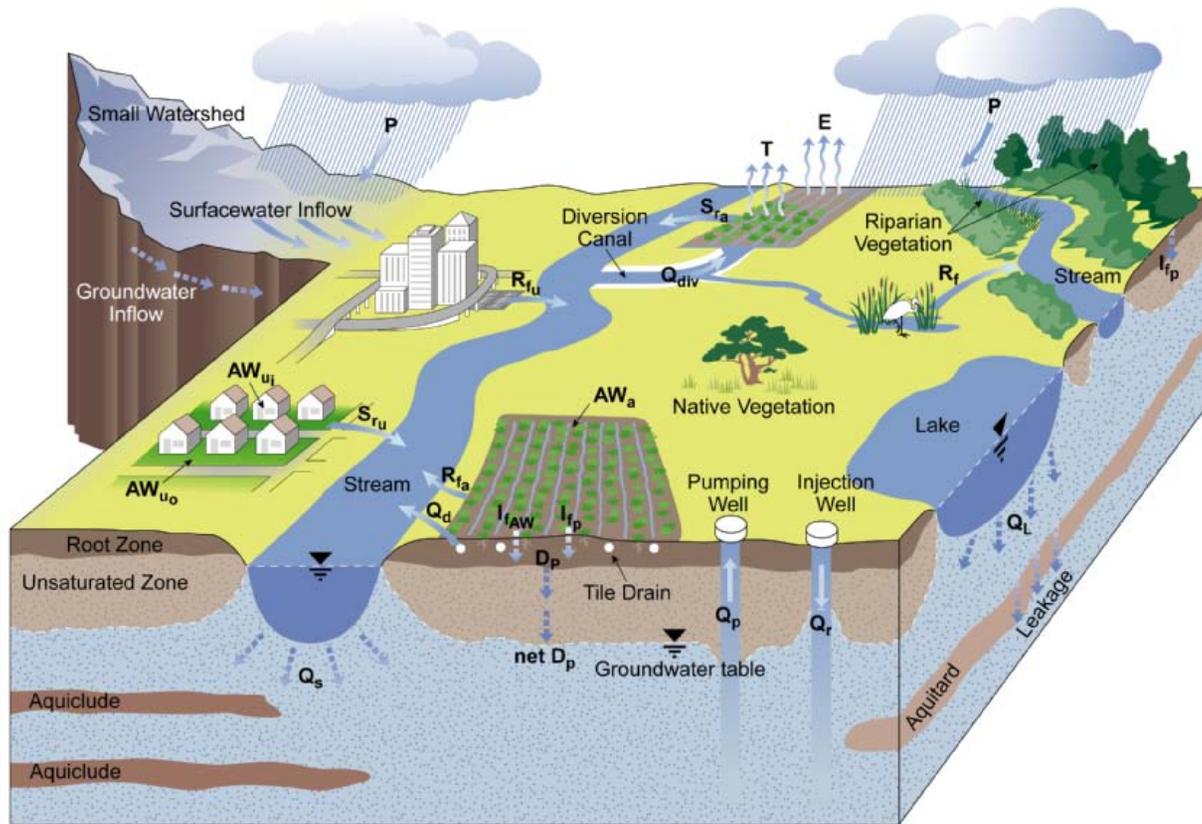

### **1.3. Summary of Current Model Features in IWFEM**

IWFEM is a water resources management and planning model that simulates

groundwater, surface water, groundwater-surface water interaction, as well as other components of the hydrologic system (Figure 1.1). Preserving the non-linear aspects of the surface and subsurface flow processes and the interactions among them is an important aspect of the current version of IWFM.

Simulation of groundwater elevations in a multi-layer aquifer system and the flows among the aquifer layers lies in the core of IWFM. Galerkin finite element method is used to solve the conservation equation for the multi-layer aquifer system. Stream flows and lake storages are also modeled in IWFM. Their interaction with the aquifer system is simulated by solving the conservation equations for groundwater, streams and lakes simultaneously.

An important aspect of IWFM that differentiates it from the other models in its class is its capability to simulate the water demand as a function of different land use and crop types, and compare it to the historical or projected amount of water supply. The agricultural water demand is computed for ponded and non-ponded crops using user-specified parameters for farm and crop management practices. Ponded crops include rice grown and decomposed using different management practices (namely rice with flooded decomposition, non-flooded decomposition or no decomposition at all). Water demands for seasonal and permanent refuges are also simulated as ponded crops since the management of these lands are very similar to those of rice fields. Non-ponded crops include all other crops that are not grown in standing water. Urban water demand is computed based on population and per-capita water usage. The user can specify stream diversion and pumping locations for the source of water supply to meet the urban and agricultural water demand. User-specified diversion and pumping amounts can be

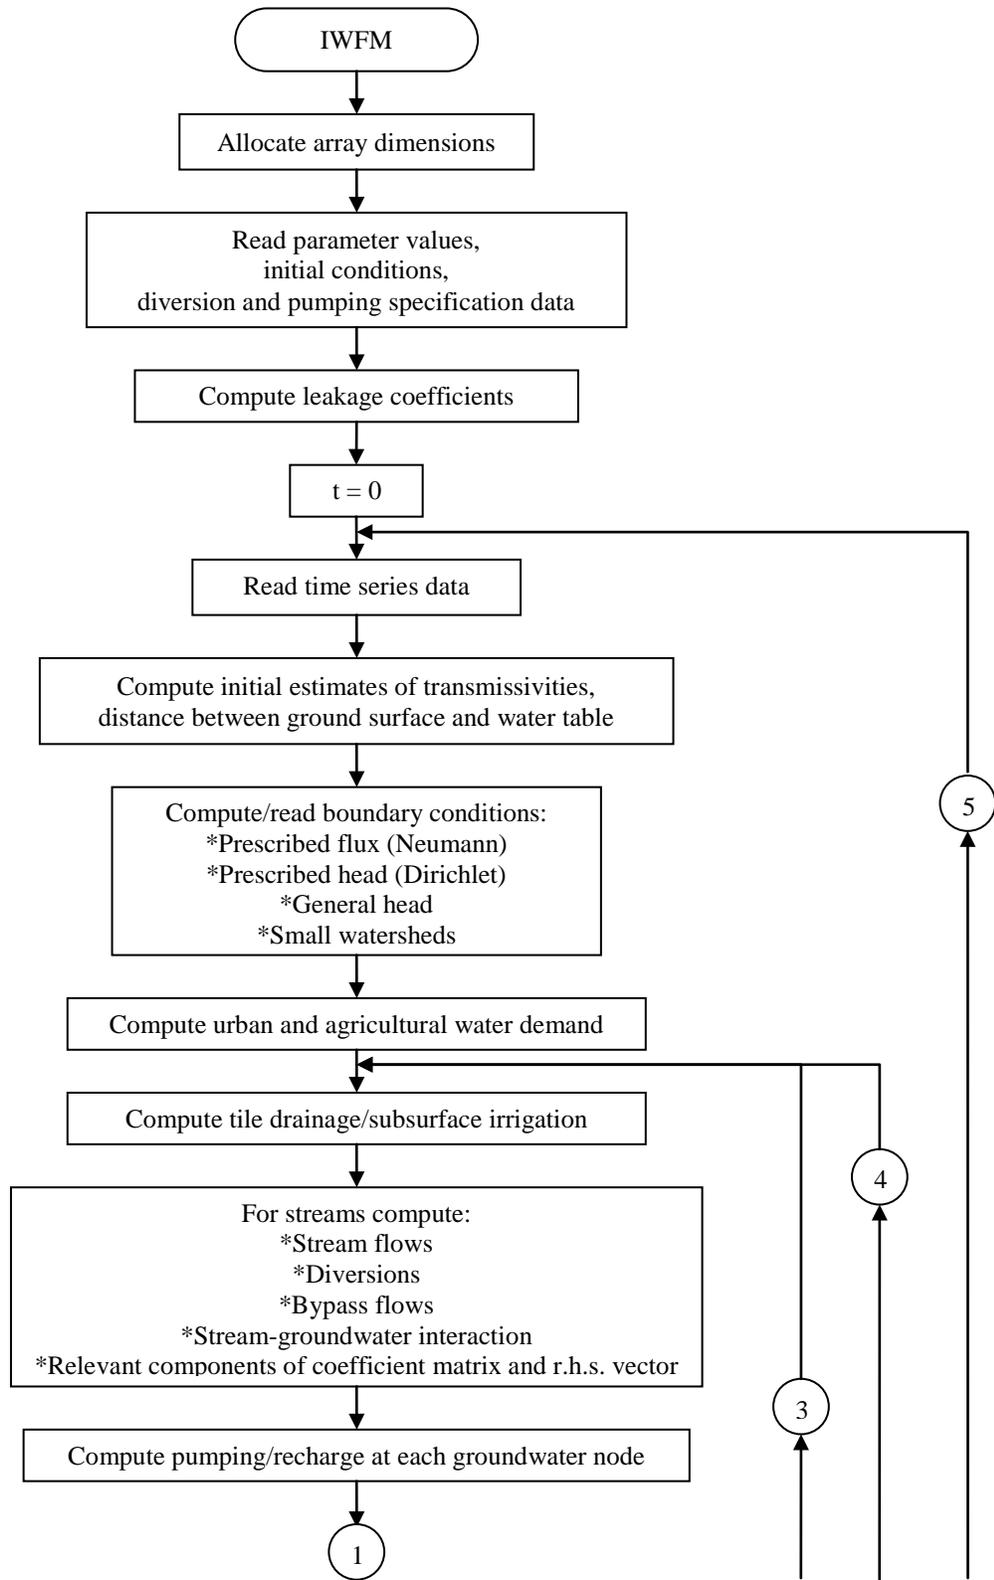

**Figure 1.1** Hydrologic processes modeled in IWFM

distributed over the modeled area for agricultural irrigation or urban municipal and industrial use. Based on the precipitation and irrigation rates, and the distribution of land use and crop types over the model domain, the infiltration, evapotranspiration and surface runoff can be computed. Vertical movement of the soil moisture through the root zone and the unsaturated zone that lies between the root zone and the saturated groundwater system can be simulated, and the recharge rates to the groundwater can be computed.

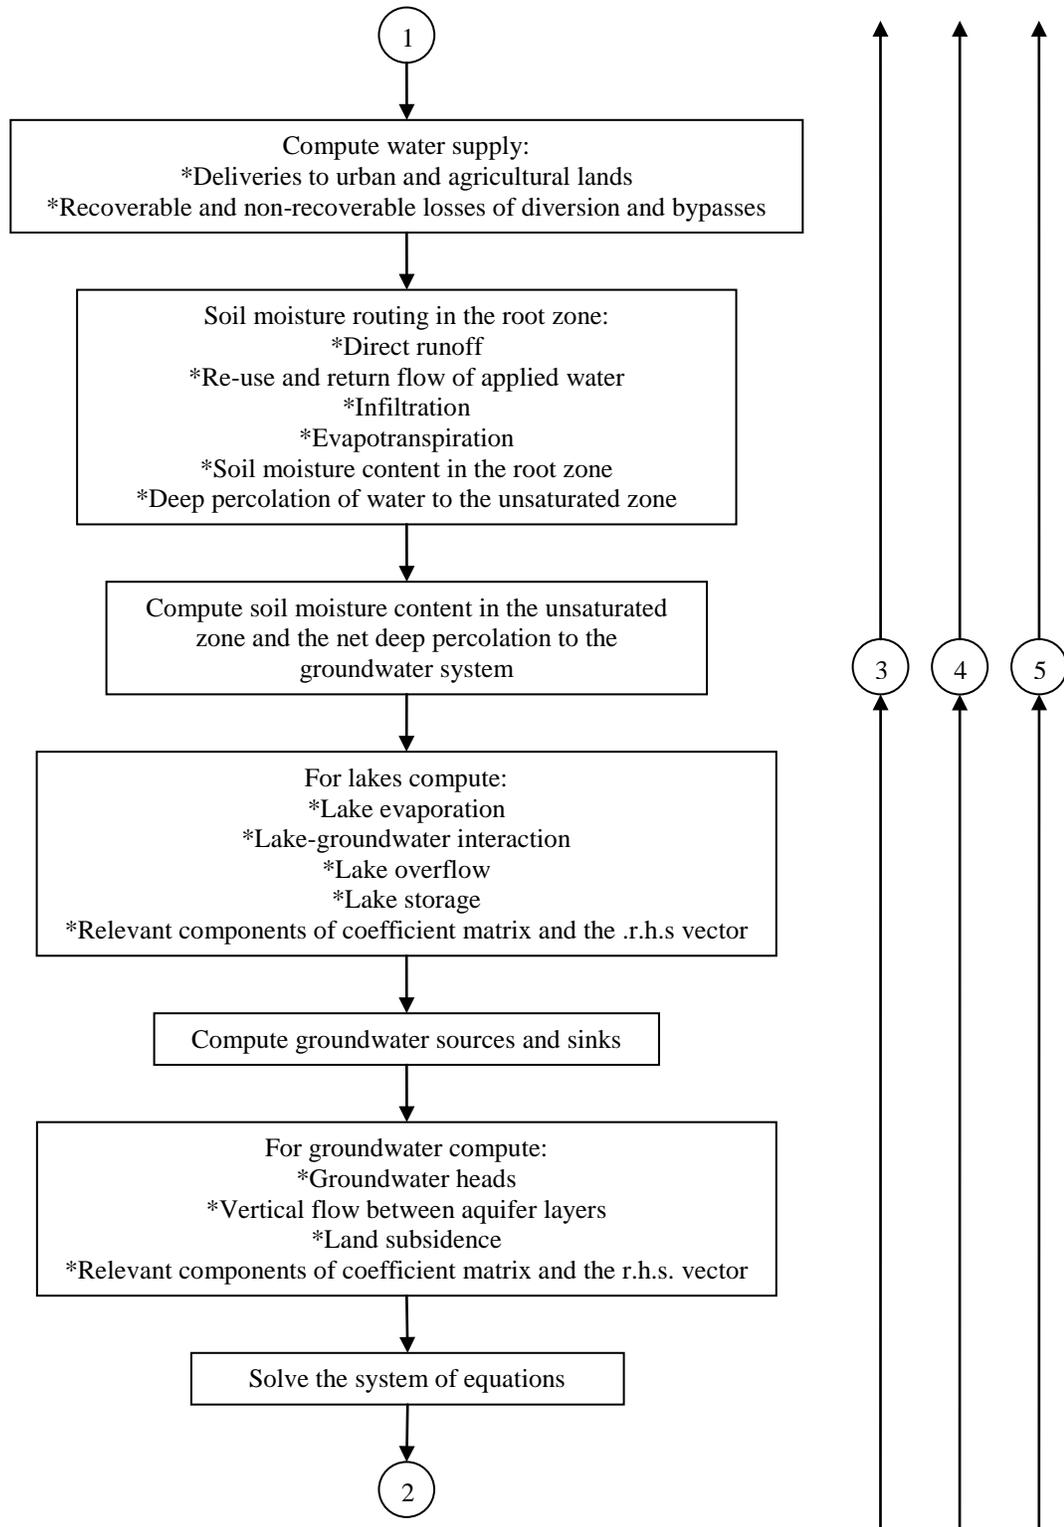

As mentioned, IWFM has the capability to compare the agricultural and urban water demands to the actual water supply (in terms of stream diversions and pumping) that is available in the modeled region from a historical or a projected point-of-view. If there is discrepancy between the water demand and the water supply (i.e. if there is a supply shortage or a supply surplus), IWFM can be used to adjust the water supplies automatically to minimize this discrepancy. The user can choose to have only diversions, only pumping amounts or both diversions and pumping adjusted to minimize the difference between the computed demand and the water supply.

IWFM allows the user to divide the entire model area into smaller sub-regions. This division can be based on hydrologic and geologic properties (e.g. individual watersheds) or on the management practices (e.g. water districts). The division of the model into smaller regions does not affect the mass distribution over the entire regions; the sub-regions are used solely for the grouping and reporting of the simulation results. The input data required by IWFM is independent of particular sub-regions. The details about the specific data requirements for IWFM are listed in the User's Manual that accompanies this document.

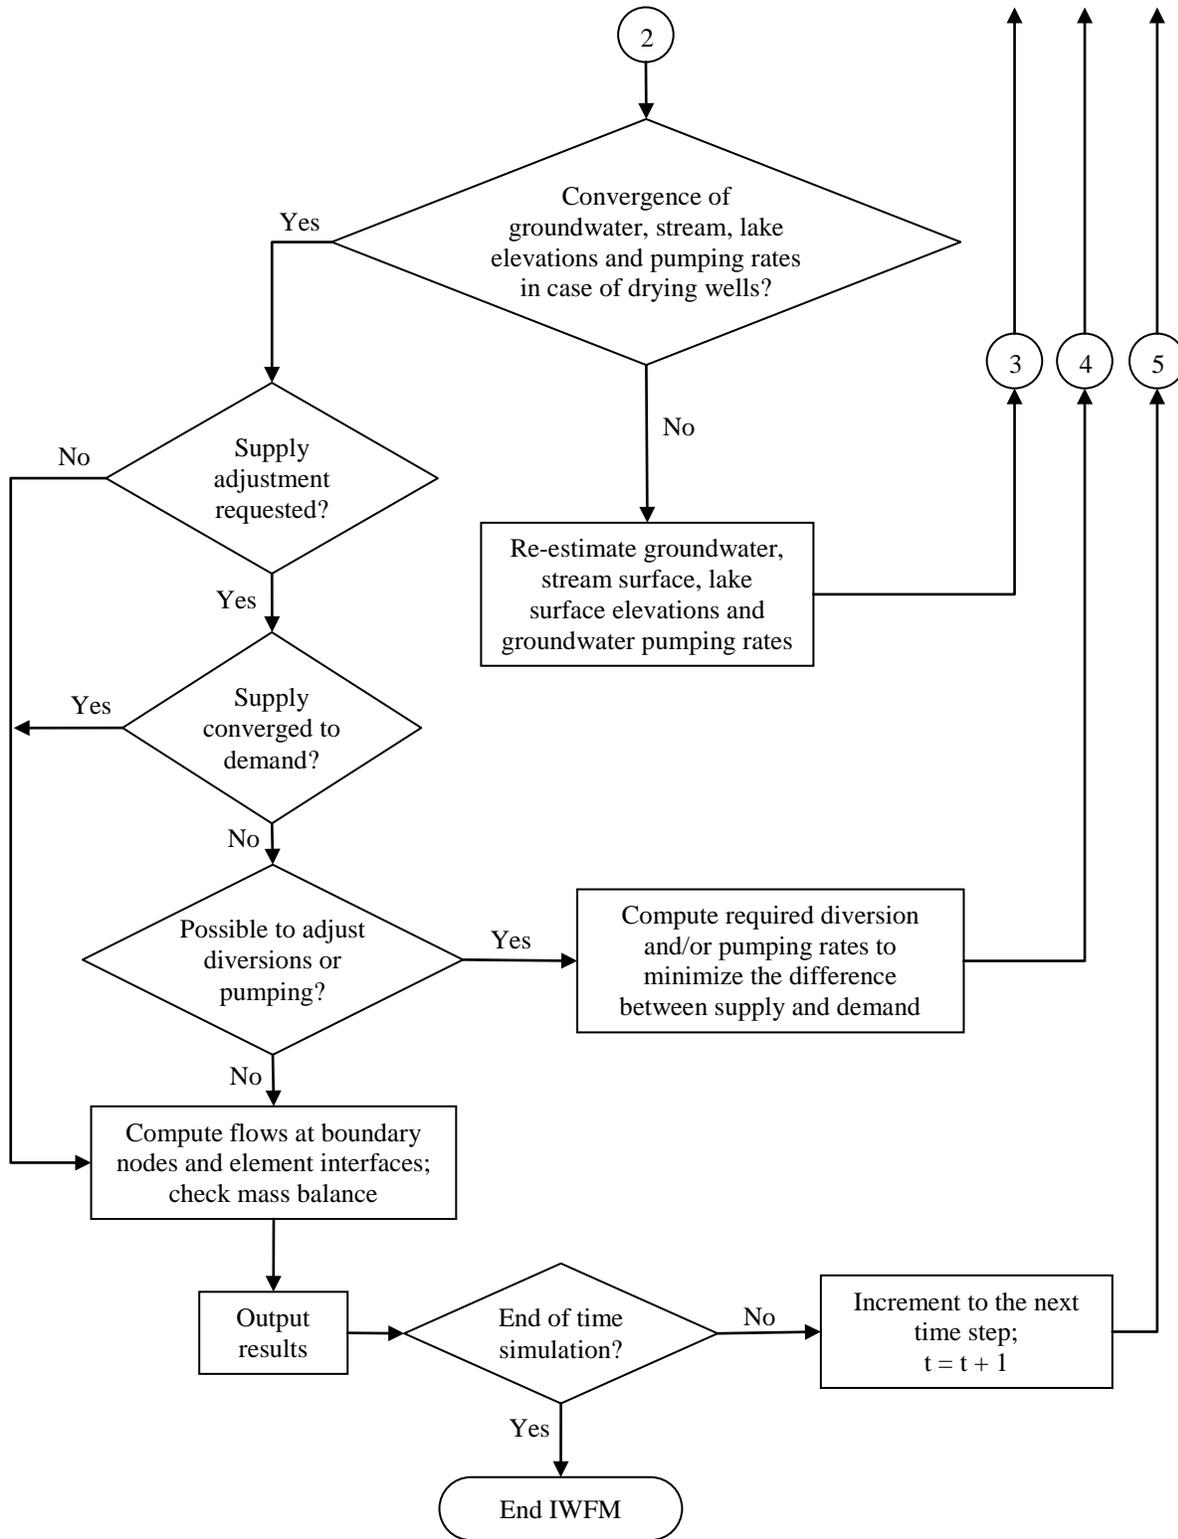

This documentation discusses the theory and methodology used in IWFM Version 4.0. Figure 1.2 is a general flowchart of the current version of IWFM. As new versions come online, revisions and additions will be made to this documentation.

**Figure 1.2** General flowchart of IWFM (*continued*)

**Figure 1.2** General flowchart of IWFM (*continued*)

## **2. Hydrological Processes Modeled in IWFM**

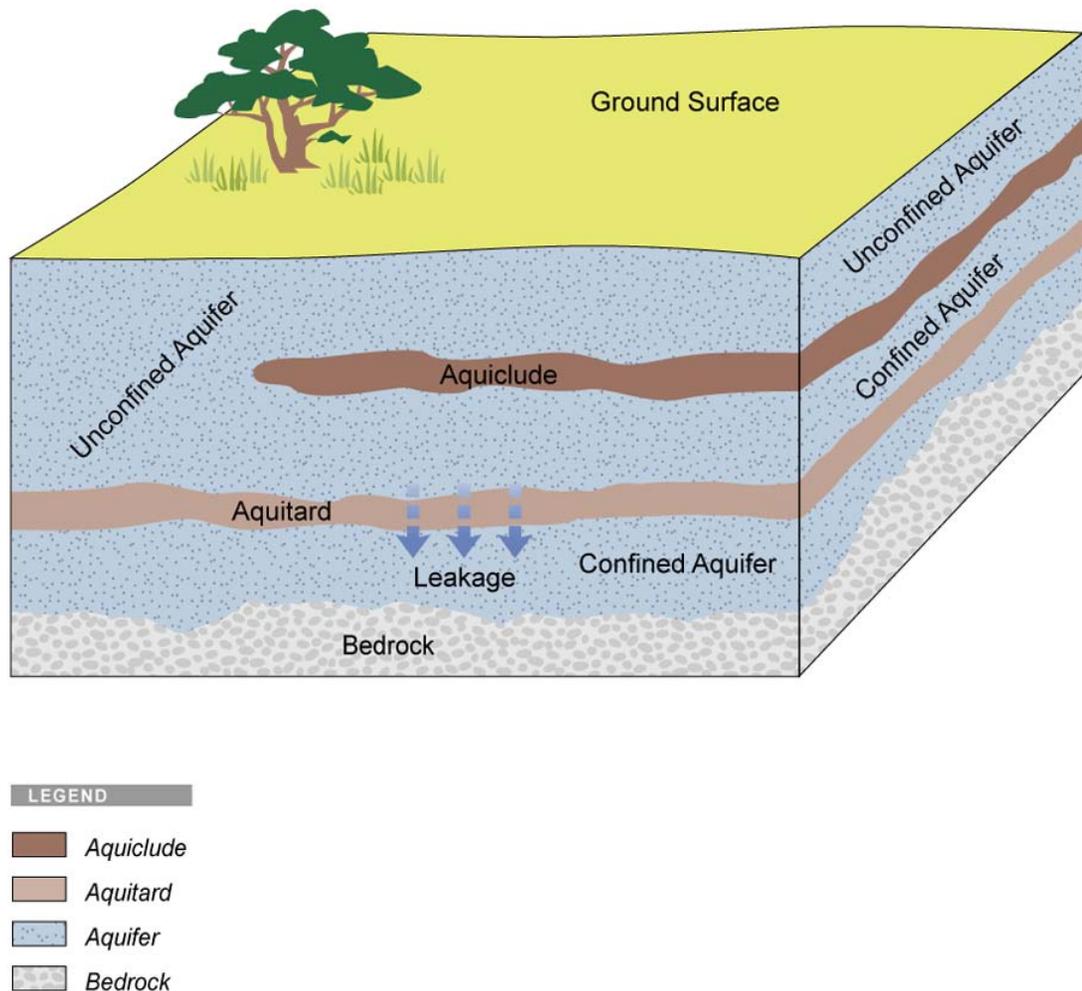

In the core of IWFM lies the simulation of regional groundwater heads. In natural hydrological systems the regional groundwater interacts with other components of the hydrologic cycle. As precipitation falls on the ground surface, it infiltrates into the soil at a rate that is dictated by the soil type, ground cover and soil moisture. The moisture in the top soil moves downward as well as it is taken out of the soil by vegetation. The downward-moving soil moisture travels through the unsaturated zone of the soil before it replenishes the groundwater.

If the infiltration capacity of the soil is less than the precipitation rate, the portion of the precipitation that is in excess of infiltration becomes surface runoff and contributes to streams and large bodies of water such as lakes. In wet periods, streams act as water sources for the aquifer system whereas in dry periods they drain water away from the aquifer. Similarly, large bodies of water, such as lakes, affect the groundwater heads during wet and dry periods. IWFM models groundwater heads, stream flows and lake storage simultaneously as well as other components of the hydrological cycle discussed above in order to simulate the interactions between these hydrological components accurately.

In this chapter, the hydrological processes that are simulated in IWFM and the theoretical background of the simulation methods along with the accompanying simplifications and assumptions are detailed. The equations used to simulate the interactions among each of these hydrological components are also explained.

## 2.1. Groundwater Flow

IWFM can simulate horizontal and vertical groundwater flow in any multi-layer aquifer system that includes a combination of confined, unconfined and leaky layers. These layers may be separated by aquitards or aquicludes (Figure 2.1). Table 2.1 gives a definition for each of these aquifer types. IWFM is also capable of simulating the change

**Figure 2.1** Multi-layer aquifer system

<b>Layer Type</b>	<b>Layer Description</b>
Confined aquifer	Aquifer bound above and below by impervious surfaces
Unconfined aquifer	Aquifer with a free water surface as the upper boundary
Leaky aquifer	Aquifer losing/gaining water through an aquitard that bounds the aquifer above/below
Aquiclude	Formation that may contain water, but unable to transmit significant quantities
Aquitard	Semi-pervious/leaky formation

**Table 2.1** Types of aquifer layers and their descriptions

in the aquifer layer types (for instance, a confined aquifer becoming unconfined) as the groundwater head levels fluctuate. The three-dimensional nature of the flow is simulated by a quasi three-dimensional approach. In this modeling approach, the depth-integrated groundwater flow equation is solved for each aquifer layer in order to compute the two-dimensional groundwater head field. Vertical flow to and from each layer is computed through approximated leakage terms that are treated as individual head dependent sources or sinks.

The equation for the conservation of mass at a cross-section of an aquifer layer is given as

$$\begin{aligned}
\frac{\partial S_s h}{\partial t} + \bar{\nabla} \cdot \bar{q} &= I_u q_u + I_d q_d + q_o - q_{sd} \\
&+ \delta(x - x_s, y - y_s) \frac{Q_{sint}}{A_s} \\
&+ \delta(x - x_{lk}, y - y_{lk}) \frac{Q_{lkint}}{A_{lk}} \\
&+ \delta(x - x_{td}, y - y_{td}) \frac{Q_{td}}{A_{td}}
\end{aligned} \tag{2.1}$$

where

$S_s$  = storativity, (dimensionless). It is equal to the storage coefficient  $S_o$ , for a confined aquifer and specific yield,  $S_y$ , for an unconfined aquifer;

$h$  = groundwater head, (L);

$\bar{q}$  = specific discharge field, ( $L^2/T$ );

$q_u$  = rate of flow into the aquifer layer from the upper adjacent layer, (L/T);

$I_u$  = indicator function for top aquifer layer, (dimensionless);

$$= \begin{cases} 1 & \text{if layer is not top aquifer layer} \\ 0 & \text{if layer is top aquifer layer} \end{cases} ;$$

$q_d$  = rate of flow into the aquifer layer from the lower adjacent layer, (L/T);

$I_d$  = indicator function for bottom aquifer layer, (dimensionless);

$$= \begin{cases} 1 & \text{if layer is not bottom aquifer layer} \\ 0 & \text{if layer is bottom aquifer layer} \end{cases} ;$$

- $\delta$  = dirac delta function, (dimensionless);
- $x_s$  = x-coordinate of a stream location, (L);
- $y_s$  = y-coordinate of a stream location, (L);
- $Q_{sint}$  = stream-groundwater interaction (see the discussion on stream flows), ( $L^3/T$ );
- $A_s$  = effective area of the stream through which stream-groundwater interaction occurs, ( $L^2$ );
- $x_{lk}$  = x-coordinate of a lake location, (L);
- $y_{lk}$  = y-coordinate of a lake location, (L);
- $Q_{lkint}$  = lake-groundwater (see the discussion on lakes), ( $L^3/T$ );
- $A_{lk}$  = effective area through which lake-groundwater interaction occurs, ( $L^2$ );
- $x_{td}$  = x-coordinate of a tile drain or subsurface irrigation system, (L);
- $y_{td}$  = y-coordinate of a tile drain or subsurface irrigation system, (L);
- $Q_{td}$  = tile drain outflow from or subsurface irrigation inflow into the groundwater system, ( $L^3/T$ );
- $A_{td}$  = effective area through which tile drain outflow or subsurface irrigation inflow is occurring, ( $L^2$ );
- $q_o$  = other sources/sinks such as pumping, recharge, subsurface inflow from adjacent small watersheds, etc., ( $L/T$ );
- $q_{sd}$  = rate of flow into storage due to the compaction of interbeds, ( $L/T$ );
- $\bar{\nabla}$  = del operator, ( $1/L$ );
- $x$  = horizontal x-coordinate, (L);

$y$  = horizontal y-coordinate, (L);  
 $t$  = time, (T).

The value of  $S_s$  for a confined aquifer is different than its value for an unconfined aquifer. To model the changing aquifer conditions (e.g. a confined aquifer becoming unconfined),  $S_s$  is kept in the time-differential term in equation (2.1). Using Darcy's equation, one can express the specific discharge in terms of the groundwater head as

$$\bar{q} = -T\bar{\nabla}h \quad (2.2)$$

where

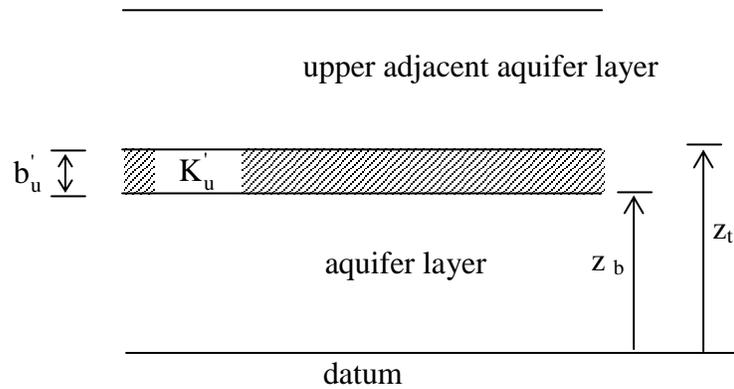

$$T = \text{transmissivity, (L}^2\text{/T)} = \begin{cases} Kb & \text{for confined aquifer} \\ K(h - z_{ab}) & \text{for unconfined aquifer} \end{cases}$$

$K$  = saturated hydraulic conductivity of the aquifer material, (L/T);  
 $b$  = thickness of the confined aquifer layer, (L);  
 $h$  = groundwater head at the unconfined aquifer, (L);  
 $z_{ab}$  = elevation of the bottom of the unconfined aquifer layer, (L).

In order to define the rate of flow into the aquifer layer from adjacent upper and lower layers, two cases have been considered: (i) adjacent aquifer layers are separated by an aquitard, and (ii) there is not an aquitard separating the adjacent aquifer layers.

### 2.1.1. Aquifer Layers Separated by an Aquitard

For this case, consider Figure 2.2 where a system of an aquifer layer, the adjacent upper layer and the aquitard separating these two layers is depicted. Bear and Verruijt

**Figure 2.2** Schematic representation of two aquifer layers separated by an aquitard

(1987) define an aquitard as a geohydrologic layer whose permeability is at least one order of magnitude smaller than that of the adjacent aquifer layers. Assuming that the aquitard is saturated throughout its thickness, the flow in the aquitard is essentially vertical and its storage is negligible, the vertical flow can be expressed as (Bear, 1972)

$$q_u = -\frac{K_u'}{b_u} \Delta h = -L_u \Delta h \quad (2.3)$$

where

$K_u'$  = vertical hydraulic conductivity of the aquitard between the aquifer layer and the upper adjacent layer, (L/T);

$b_u'$  = thickness of the aquitard between the aquifer layer and the upper adjacent layer, (L);

$\Delta h$  = head difference between the top and the bottom of the aquitard, (L);

$L_u$  = leakage coefficient between the aquifer layer and the upper adjacent layer, (1/T).

Therefore, from equation (2.3), the leakage coefficient,  $L_u$ , is expressed as

$$L_u = \frac{K'_u}{b'_u} \quad (2.4)$$

The head difference,  $\Delta h$ , between the top and the bottom of the aquitard depends on the hydraulic head in the aquifer layer and the upper adjacent aquifer layer (Figure 2.2). It can be written as

$$\Delta h = \begin{cases} h - h_u & \text{if } h \geq z_b ; h_u > z_t \\ z_b - h_u & \text{if } h < z_b ; h_u > z_t \\ h - z_t & \text{if } h \geq z_b ; h_u = z_t \\ 0 & \text{if } h < z_b ; h_u = z_t \end{cases} \quad (2.5)$$

where

$h$  = groundwater head at the aquifer in consideration, (L);

$h_u$  = groundwater head at the upper adjacent aquifer, (L);

$z_b$  = bottom elevation of the aquitard, (L);

$z_t$  = top elevation of the aquitard, (L).

Similarly, the flow rate into the aquifer layer from a lower adjacent aquifer that is separated by an aquitard can be expressed as

$$q_d = -L_d \Delta h \quad (2.6)$$

where

$L_d$  = leakage coefficient between the aquifer layer and the lower adjacent layer, (1/T);

$\Delta h$  = head difference between the top and the bottom of the aquitard that separates the aquifer and the lower adjacent aquifer, (L).

The leakage coefficient and head difference in equation (2.6) is given, respectively, as

$$L_d = \frac{K'_d}{b'_d} \quad (2.7)$$

$$\Delta h = \begin{cases} h - h_d & \text{if } h \geq z_t ; h_d \geq z_b \\ z_t - h_d & \text{if } h = z_t ; h_d \geq z_b \\ h - z_t & \text{if } h \geq z_t ; h_d < z_b \\ 0 & \text{if } h = z_t ; h_d < z_b \end{cases} \quad (2.8)$$

where

$K'_d$  = vertical hydraulic conductivity of the aquitard between the aquifer layer and the lower adjacent layer, (L/T);

$b'_d$  = thickness of the aquitard between the aquifer layer and the lower adjacent layer, (L);

$h$  = groundwater head at the aquifer layer in consideration, (L);

$h_d$  = groundwater head at the lower adjacent aquifer layer, (L).

Note that, in equation (2.8),  $z_t$  and  $z_b$  represent the top and bottom elevations of the semi-confining layer that underlies the aquifer layer in consideration.

### 2.1.2. Aquifer Layers that are not Separated by an Aquitard

For the second case where two adjacent aquifer layers have vertical hydraulic conductivities that have the same order of magnitudes with no aquitard separating them,

consider Figure 2.3. Due to the continuity of the vertical flow at the interface between two layers, one can write

$$q_u = -\frac{K_u}{b_u/2} \Delta h_1 = -\frac{K}{b/2} \Delta h_2 = -L_u \Delta h \quad (2.9)$$

and

$$\Delta h = \Delta h_1 + \Delta h_2 \quad (2.10)$$

where

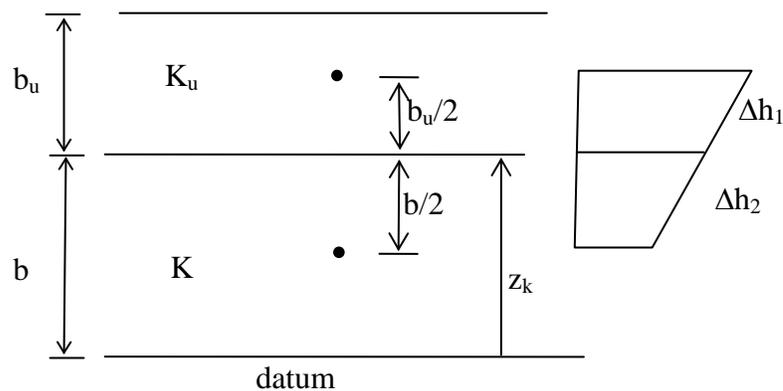

$K_u$  = vertical hydraulic conductivity of the upper adjacent aquifer layer, (L/T);

$b_u$  = thickness of the upper adjacent aquifer layer, (L);

$K$  = vertical hydraulic conductivity of the aquifer layer in consideration, (L/T);

$b$  = thickness of the aquifer layer in consideration, (L);

$h$  = groundwater head at the aquifer layer in consideration, (L);

**Figure 2.3** Schematic representation of two aquifer layers that are not separated with an aquitard

- $h_u$  = groundwater head at the upper adjacent aquifer layer, (L);  
 $L_u$  = leakage coefficient between the aquifer layer and upper adjacent aquifer layer, (1/T);  
 $\Delta h$  = head difference between the aquifer layer and the upper adjacent aquifer layer, (L).

Substituting equation (2.9) into (2.10) for  $\Delta h_1$  and  $\Delta h_2$  and solving for the leakage coefficient,  $L_u$ , one obtains the harmonic mean of the leakage coefficients of the aquifer layer in consideration and the upper adjacent aquifer layer:

$$L_u = \frac{1}{0.5 \left( \frac{b_u}{K_u} + \frac{b}{K} \right)} \quad (2.11)$$

Also, the head difference between two aquifer layers can be expressed similar to equation (2.5) as

$$\Delta h = \begin{cases} h - h_u & \text{if } h \geq z_k ; h_u > z_k \\ z_k - h_u & \text{if } h < z_k ; h_u > z_k \\ h - z_k & \text{if } h \geq z_k ; h_u = z_k \\ 0 & \text{if } h < z_k ; h_u = z_k \end{cases} \quad (2.12)$$

where

- $z_k$  = elevation of the interface between the adjacent aquifer layers, (L).

A similar expression can be obtained for the leakage coefficient and the head difference between the aquifer layer and the lower adjacent aquifer layer when they are not separated by an aquitard as

$$L_d = \frac{1}{0.5 \left( \frac{b_d}{K_d} + \frac{b}{K} \right)} \quad (2.13)$$

$$\Delta h = \begin{cases} h - h_d & \text{if } h \geq z_k ; h_d \geq z_k \\ z_k - h_d & \text{if } h = z_k ; h_d \geq z_k \\ h - z_k & \text{if } h \geq z_k ; h_d < z_k \\ 0 & \text{if } h = z_k ; h_d < z_k \end{cases} \quad (2.14)$$

After substituting equations (2.2), (2.3) and (2.6) into (2.1) and rearranging, one obtains the groundwater flow equation that is used in IWFEM:

$$\begin{aligned} 0 = & \frac{\partial S_s h}{\partial t} - \bar{\nabla} \cdot (\mathbf{T} \bar{\nabla} h) + I_u L_u \Delta h^u + I_d L_d \Delta h^d - q_o + q_{sd} \\ & - \delta(x - x_s, y - y_s) \frac{Q_{sint}}{A_s} \\ & - \delta(x - x_{lk}, y - y_{lk}) \frac{Q_{lkint}}{A_{lk}} \\ & - \delta(x - x_{td}, y - y_{td}) \frac{Q_{td}}{A_{td}} \end{aligned} \quad (2.15)$$

where the terms  $\Delta h^u$  and  $\Delta h^d$  are introduced in order to differentiate between the head difference between the aquifer and the upper adjacent layer, and the head difference between the aquifer and the lower adjacent layer, respectively. Based on the stratigraphic characteristics of the aquifer system, equations (2.4) and (2.7) are used for leakage coefficients when adjacent aquifer layers are separated by an aquitard. Equations (2.11) and (2.13) are used when adjacent layers are not separated by an aquitard.

Equation (2.15) is a partial differential equation that models unsteady groundwater flow in a multi-layer aquifer system that consists of confined and/or unconfined layers. These layers may be separated by semi-confining layers. Equation (2.15) is non-linear if the aquifer layer is unconfined and linear if it is confined. Equation (2.15) also takes into account the effect of aquifer interaction with streams and lakes, and the effect of tile drainage and subsurface irrigation on the groundwater heads.

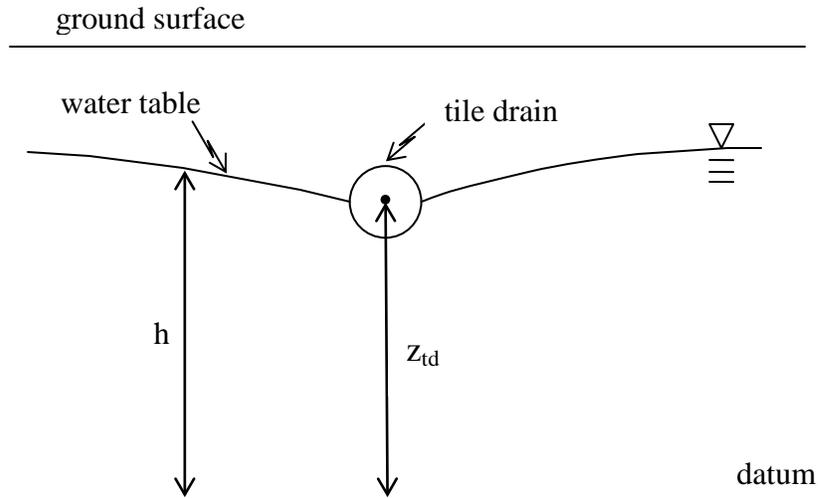

To define a well-posed problem, equation (2.15) should be coupled with initial and boundary conditions for each aquifer layer. The boundary conditions that can be defined in IWFM are (i) specified flux (Neumann), (ii) specified head (Dirichlet), and (iii) general head boundary conditions.

## **2.2. Tile Drainage and Subsurface Irrigation**

Tile drainage is often used in farm lands in order to increase the groundwater drainage where the natural drainage of the soil is not fast enough to maintain desired agricultural conditions. Tile drains are located beneath the surface of the soil. The term tile drain is used since they are in the form of clayware pipes, which are made from clay tiles (Smedema and Rycroft, 1983). Tile drains are used for the drainage of water applied to agricultural lands for the following reasons: (i) they do not interfere with farming operations since their location is beneath the surface, and (ii) there is no loss of farming area due to the drainage system (Smedema and Rycroft, 1983; Luthin, 1973). Figure 2.4 shows a schematic representation of a tile drain.

IWFM can also simulate the effect of subsurface irrigation on the groundwater heads. Figure 2.5 illustrates subsurface irrigation, where the direction of flow is from the irrigation pipes to the groundwater. Subsurface irrigation is beneficial for deep rooted crops and trees in arid areas to avoid excessive evaporation.

Simulations of tile drains and subsurface irrigation are similar except that for tile drains flow direction is always from groundwater to tile drain, whereas for subsurface irrigation system the direction is always from the irrigation pipe towards the

**Figure 2.4** Schematic representation of a tile drain

groundwater. The difference of the groundwater head and tile drain elevation (or head at the subsurface irrigation pipe) is multiplied by a conductance term to approximate the flow between groundwater and tile drain (or subsurface irrigation pipe):

$$Q_{td} = C_{td} (z_{td} - h) \quad (2.16)$$

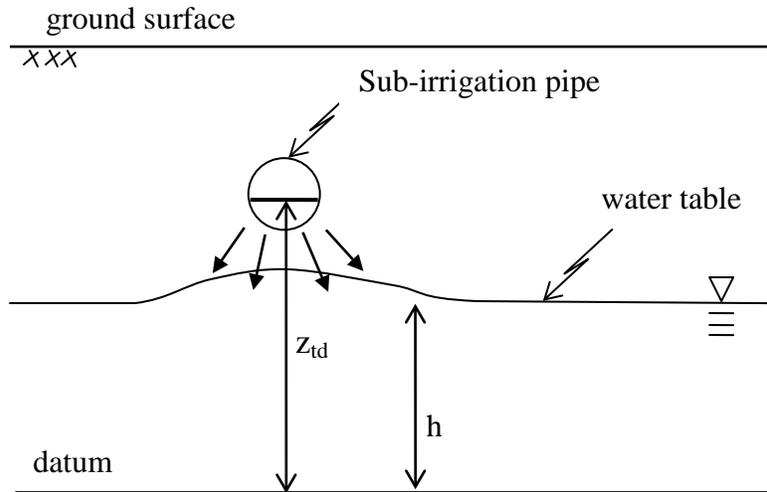

where

$Q_{td}$  = flow between groundwater and tile drain or subsurface irrigation pipe, ( $L^3/T$ );

$C_{td}$  = conductance of the interface material between the tile drain/subsurface irrigation pipe and the aquifer material, ( $L^2/T$ );

$z_{td}$  = elevation of the tile drain or the head at the subsurface irrigation pipe, (L);

$h$  = groundwater head at the location of tile drain or subsurface irrigation pipe, (L).

**Figure 2.5** Flow from a subsurface irrigation pipe to the groundwater

The flow term,  $Q_{td}$ , is negative in modeling tile drains and positive in modeling subsurface irrigation.

The conductance term,  $C_{td}$ , can be expressed as

$$C_{td} = \frac{K_{td}}{d_{td}} A_{td} \quad (2.17)$$

where

$K_{td}$  = hydraulic conductivity of the interface material between the tile drain/subsurface irrigation pipe and aquifer material, (L/T);

$d_{td}$  = thickness of the interface material, (L);

$A_{td}$  = effective area through which tile drain outflow or subsurface irrigation inflow is occurring, ( $L^2$ ).

If dependable field measurements are available, they may be used to calculate the conductance,  $C_{id}$ . In many cases, however, a conductance value must be chosen somewhat arbitrarily and adjusted during model calibration.

### **2.3. Land Subsidence**

IWFM accounts for changes in storage due to land subsidence. The change in soil structure, which causes subsidence, primarily occurs from pumping large amounts of groundwater in a given area. Modeling land subsidence is an important feature of IWFM since storage changes impact the available water supply.

The change in storage can be temporary or permanent, depending upon the amount of stress placed on the soils. A temporary change in storage means that the soils were not permanently displaced and the elasticity of the soil is preserved. Given the compaction is elastic, the soil may still expand. Extraction of large amounts of water from the aquifer may increase the effective stress of the soils beyond a threshold value, causing permanent displacement of soils and a permanent decrease in the storage capacity of the aquifer.

IWFM calculates the groundwater head changes due to subsidence in relation to the vertical compaction of interbeds. Interbeds are lenses that have poor permeability within a relatively permeable aquifer. The following three items are used as criteria when defining an interbed (Leake and Prudic, 1988):

- The hydraulic conductivity of the interbed is significantly lower than the hydraulic conductivity of the aquifer material.

- The lateral extent of the interbed must be small enough so that it is not considered a confining bed that separates adjacent aquifers.
- The interbed thickness must be small in comparison to its lateral extent.

Land subsidence is a function of the change in the effective stress, elastic and inelastic specific storages of the interbed, and the initial interbed thickness, given that the geostatic and the hydrostatic pressures over the interbed are constant. The elastic change in the interbed thickness can be written as (Riley, 1969; Helm, 1975)

$$\Delta b_{se} = \frac{\Delta p'}{\gamma_w} S_{se} b_o \quad (2.18)$$

where

$\Delta b_{se}$  = elastic change in interbed thickness, positive for compaction and negative for expansion, (L);

$\Delta p'$  = change in effective stress, positive for increase and negative for decrease, (F/L<sup>2</sup>);

$\gamma_w$  = unit weight of water, (F/L<sup>3</sup>);

$S_{se}$  = elastic specific storage, (1/L);

$b_o$  = the initial thickness of the interbed, (L).

For an interbed located in an aquifer where geostatic pressure is constant, the change in effective stress as a function of the change in head can be expressed as (Poland and Davis, 1969)

$$\Delta p' = -\gamma_w \Delta h \quad (2.19)$$

where

$\Delta h$  = change in head; positive for increase and negative for decrease in head, (L).

Substituting (2.19) into (2.18), one can express the change in interbed thickness in terms of change in the head as

$$\Delta b_{se} = -\Delta h S_{se} b_o \quad (2.20)$$

Similarly, inelastic change in the interbed thickness can be approximately related to the change in head at an aquifer where geostatic pressure is constant as (Leake and Prudic, 1988)

$$\Delta b_{si} = -\Delta h S_{si} b_o \quad (2.21)$$

where

$\Delta b_{si}$  = inelastic change in interbed thickness, positive for compaction and negative for expansion, (L);

$S_{si}$  = inelastic specific storage, (1/L).

The total compaction, i.e. elastic and inelastic compaction, can be computed by adding the elastic and inelastic compactions computed by equations (2.20) and (2.21).

Equations (2.20) and (2.21) require that the geostatic pressure in the aquifer is constant. Geostatic pressure is constant in confined aquifers but it changes in an unconfined aquifer as the water table fluctuates. In IWFM it is assumed that the change in geostatic pressure is negligible in unconfined aquifers so that equations (2.20) and (2.21) can be used for modeling the land subsidence in unconfined as well as confined aquifers. Normally, the compaction is less for an unconfined aquifer compared to the compaction in a confined aquifer. By using the assumption that equations (2.20) and

(2.21) are applicable to unconfined aquifers, the actual compaction in unconfined aquifers is slightly overestimated in IWFM.

### 2.3.1. Flow into Groundwater Storage due to Land Subsidence

The groundwater flow equation used in IWFM is given in equation (2.15). The first term on the right hand side of equation (2.15) represents the flow rate into groundwater storage due to fluctuating head values. To incorporate the flow into storage due to interbed compaction, an additional term,  $q_{sd}$ , has been included in equation (2.15). This additional term can be expressed as (Leake and Prudic, 1988)

$$q_{sd} = S'_s \frac{\partial h}{\partial t} \quad (2.22)$$

where

$q_{sd}$  = rate of flow into or out of storage due to compaction or expansion of interbeds, (L/T);

$S'_s$  = skeletal storativity of interbeds, (dimensionless).

The skeletal storativity value in (2.22) varies between the elastic and inelastic specific storage values multiplied by the interbed thickness,  $b_o$ , depending on the relation of the head to the pre-consolidation head. If the head is above the pre-consolidation head,  $S'_s$  takes the value of elastic specific storage multiplied by the interbed thickness and if the head falls below the pre-consolidation head, it takes the value of inelastic specific storage multiplied by the interbed thickness:

$$S'_s = \begin{cases} S_{se}b_o & \text{if } h > h_c \\ S_{si}b_o & \text{if } h \leq h_c \end{cases} \quad (2.23)$$

where

$h_c$  = pre-consolidation head.

The pre-consolidation head value is also adjusted during the simulation period. It is assigned the most recent lowest head value if the head falls below the pre-compaction head. Equations (2.15) and (2.22) reveal that when the rate of change of groundwater head is positive (i.e. increasing groundwater head) flow out of the storage will occur due to expansion of the interbeds. If the rate of change of head is negative (i.e. decreasing groundwater head) flow into the groundwater storage will occur due to the compaction of the interbeds. If the head falls below the pre-consolidation head,  $h_c$ , the compaction is irreversible. If the head stays above the pre-consolidation then the interbeds will expand again upon recharge of the aquifer.

## 2.4. Initial and Boundary Conditions

The solution of the groundwater flow equation (2.15) requires specification of boundary and initial conditions, which constrain the problem and make solutions unique. Initial and boundary conditions are not only necessary in solving the groundwater equation, but the accuracy is important as well. If inconsistent or incomplete boundary conditions are specified, the problem is ill defined (Wang and Anderson, 1982).

### 2.4.1. Initial Conditions

The solution of equation (2.15) requires the knowledge of groundwater head values at the beginning of the simulation period. Therefore,  $h(x, y, t = 0)$  needs to be specified for all aquifer layers by the user.

### 2.4.2. Specified Flux (Neumann)

A Neumann boundary condition is applied when the flow is known across surfaces bounding the domain. Given a specified flux boundary, the flux normal to the boundary is prescribed for all the points of the boundary as a function of location and time:

$$q_{\Gamma} = -T \frac{\partial h}{\partial n} = f(x, y, t) \quad (2.24)$$

where

- $q_{\Gamma}$  = specified flux at the boundary, ( $L^2/T$ );
- $T$  = transmissivity, ( $L^2/T$ );
- $h$  = groundwater head at the boundary, ( $L$ );
- $n$  = distance that is measured perpendicular and outward to the boundary, ( $L$ );
- $f(x,y,t)$  = known function for all points on the part of the boundary where flux is specified, ( $L^2/T$ ).

This type of boundary condition typically occurs in an aquifer adjacent to bedrock, where there is no flux. Aquifers adjacent to another source of water with fixed

flux into or out of the aquifer system also involve this type of boundary condition.

### 2.4.3. Specified Head (Dirichlet)

A Dirichlet boundary condition is set when the hydraulic head is known for surfaces bounding the flow domain. This type of boundary condition assumes a constant head value for the designated points of the boundary. For instance, a specified head boundary may occur when the flow domain is adjacent to an open body of water. At every point on this type of boundary, the piezometric head is the same as the head in the aquifer at the point adjacent to it. In groundwater flow, this occurs at the interface between a saturated porous medium and a river, lake or sea (Bear, 1972).

### 2.4.4. General Head

The general head boundary condition is applied when the head value is known at a distance from the boundary nodes. The known head value is usually at a body of water located at a given distance from the boundary nodes. It can also come from a subsurface source, such as the groundwater head at a nearby groundwater basin. The general head boundary inflow at a finite element node can be expressed as

$$Q_{\text{GHB}} = \frac{K_{\Gamma} A_{\Gamma}}{d_{\Gamma}} (h_{\text{GHB}} - h_{\Gamma}) \quad (2.25)$$

where

$Q_{\text{GHB}}$  = general head boundary flow, ( $L^3/T$ );

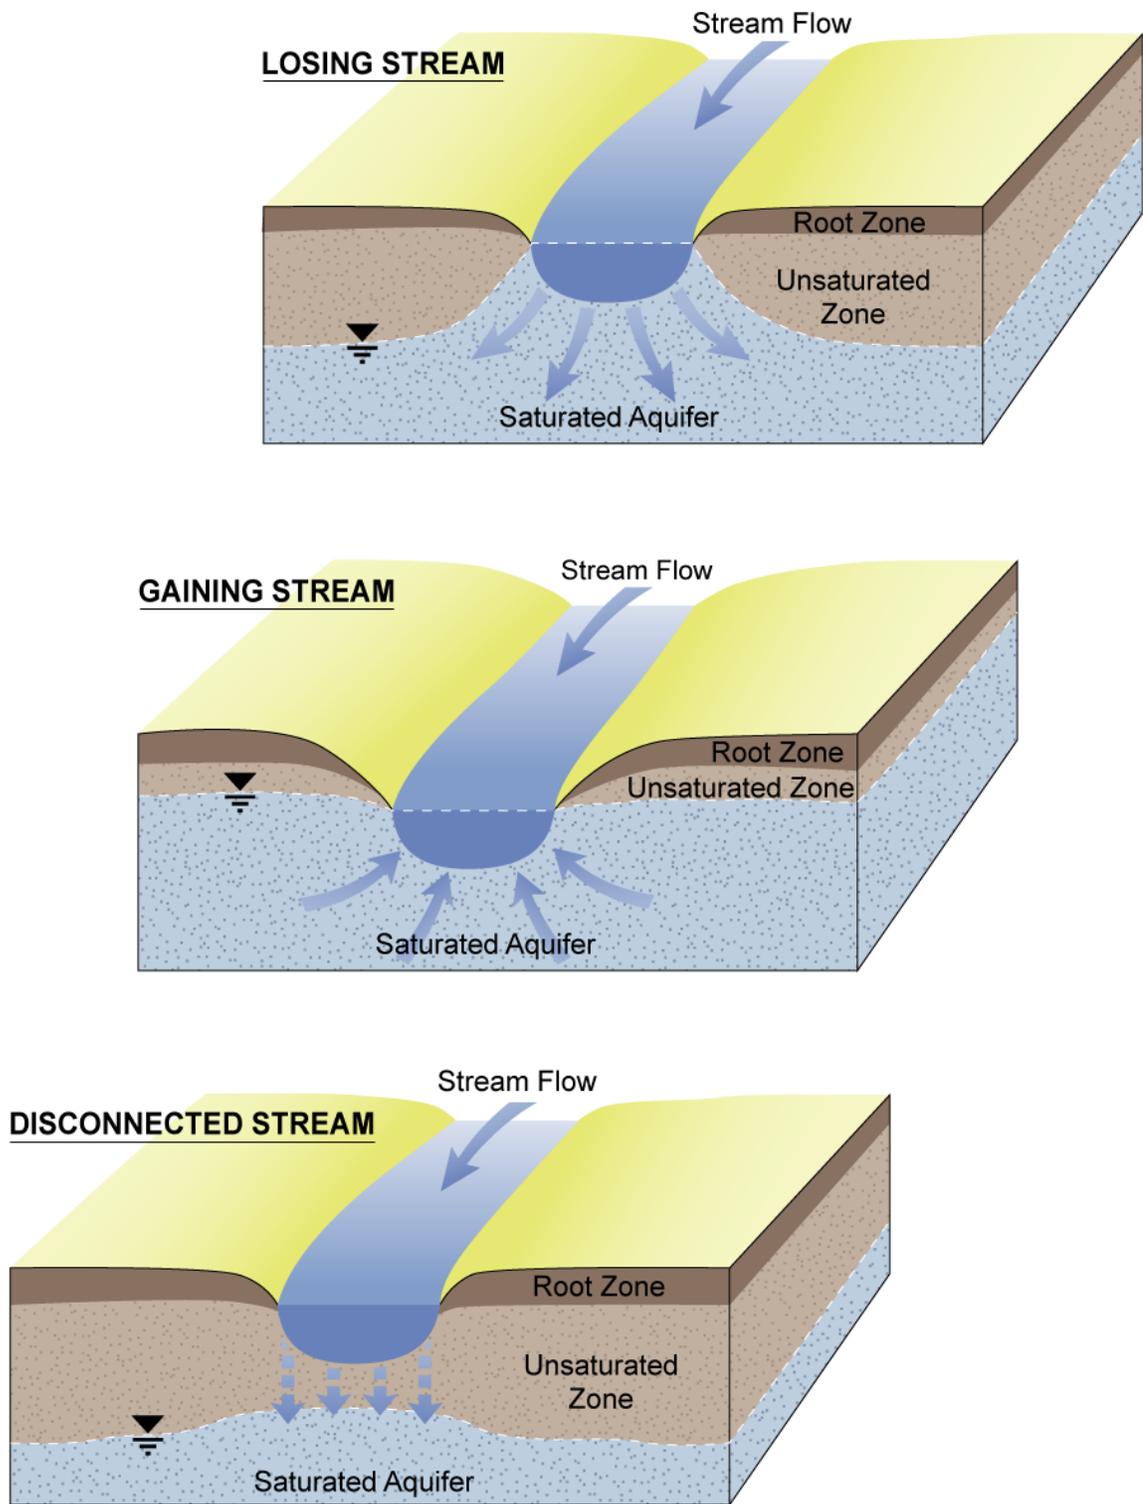

$K_{\Gamma}$  = hydraulic conductivity of the aquifer at the boundary, ( $L/T$ );

- $A_{\Gamma}$  = cross-sectional area at the boundary that flow passes through, ( $L^2$ );
- $d_{\Gamma}$  = distance between the boundary and the location of the known head, (L);
- $h_{\Gamma}$  = head value at the boundary, (L);
- $h_{\text{GHB}}$  = head at the nearby surface water body or aquifer, (L).

## 2.5. Stream Flows

Streams are an important component of the hydrological cycle. During the periods when groundwater heads are low, they contribute water to the groundwater and during periods when the groundwater heads are high, they drain water away (Figure 2.6). In regions where agricultural and urban development is high, they are also used as a source of water supply. A portion of the water that is diverted from the streams and used to meet agricultural and urban water demands seeps into the groundwater at locations far from streams. This further complicates the stream-groundwater system.

IWFM incorporates a stream routing package that simulates the stream flows as a function of flow from the upstream tributaries and reaches, surface runoff, agricultural and urban return flow, diversions and bypasses, flow from upstream lakes and the exchange of water between the stream and the groundwater. The stream system is divided into segments that are termed *stream reaches*. Each reach consists of multiple stream nodes. Each stream node represents a section of the stream reach which is termed as *stream segment*. Stream flows are simulated at each stream node. An example of the representation of a natural stream system by stream nodes and stream segments is

**Figure 2.6** Stream-groundwater interaction scenarios

depicted in Figure 2.7. In Figure 2.7.c, stream segments that are represented by stream nodes are shown between two consecutive dashed lines. It should be noted that at a confluence there are as many nodes as the number of stream reaches meeting at the confluence. Even though stream nodes at a confluence are located at the same coordinates, the stream segments that they represent are different (Figure 2.7.c).

In simulating the stream flows, IWFM uses the continuity equation, where storage at stream node  $i$  is assumed to be zero:

$$0 = Q_{in} - Q_{out} \quad (2.26)$$

and

$$Q_{in} = \sum_j Q_{s_j} + R_f + S_r + Q_{ws} + Q_{brs} + Q_{td} + Q_{lko} + Q_h \quad (2.27)$$

$$Q_{out} = Q_{bdiv} + Q_{sint} + Q_{s_i} \quad (2.28)$$

$$Q_{bdiv} = Q_b + Q_{div} \quad (2.29)$$

where

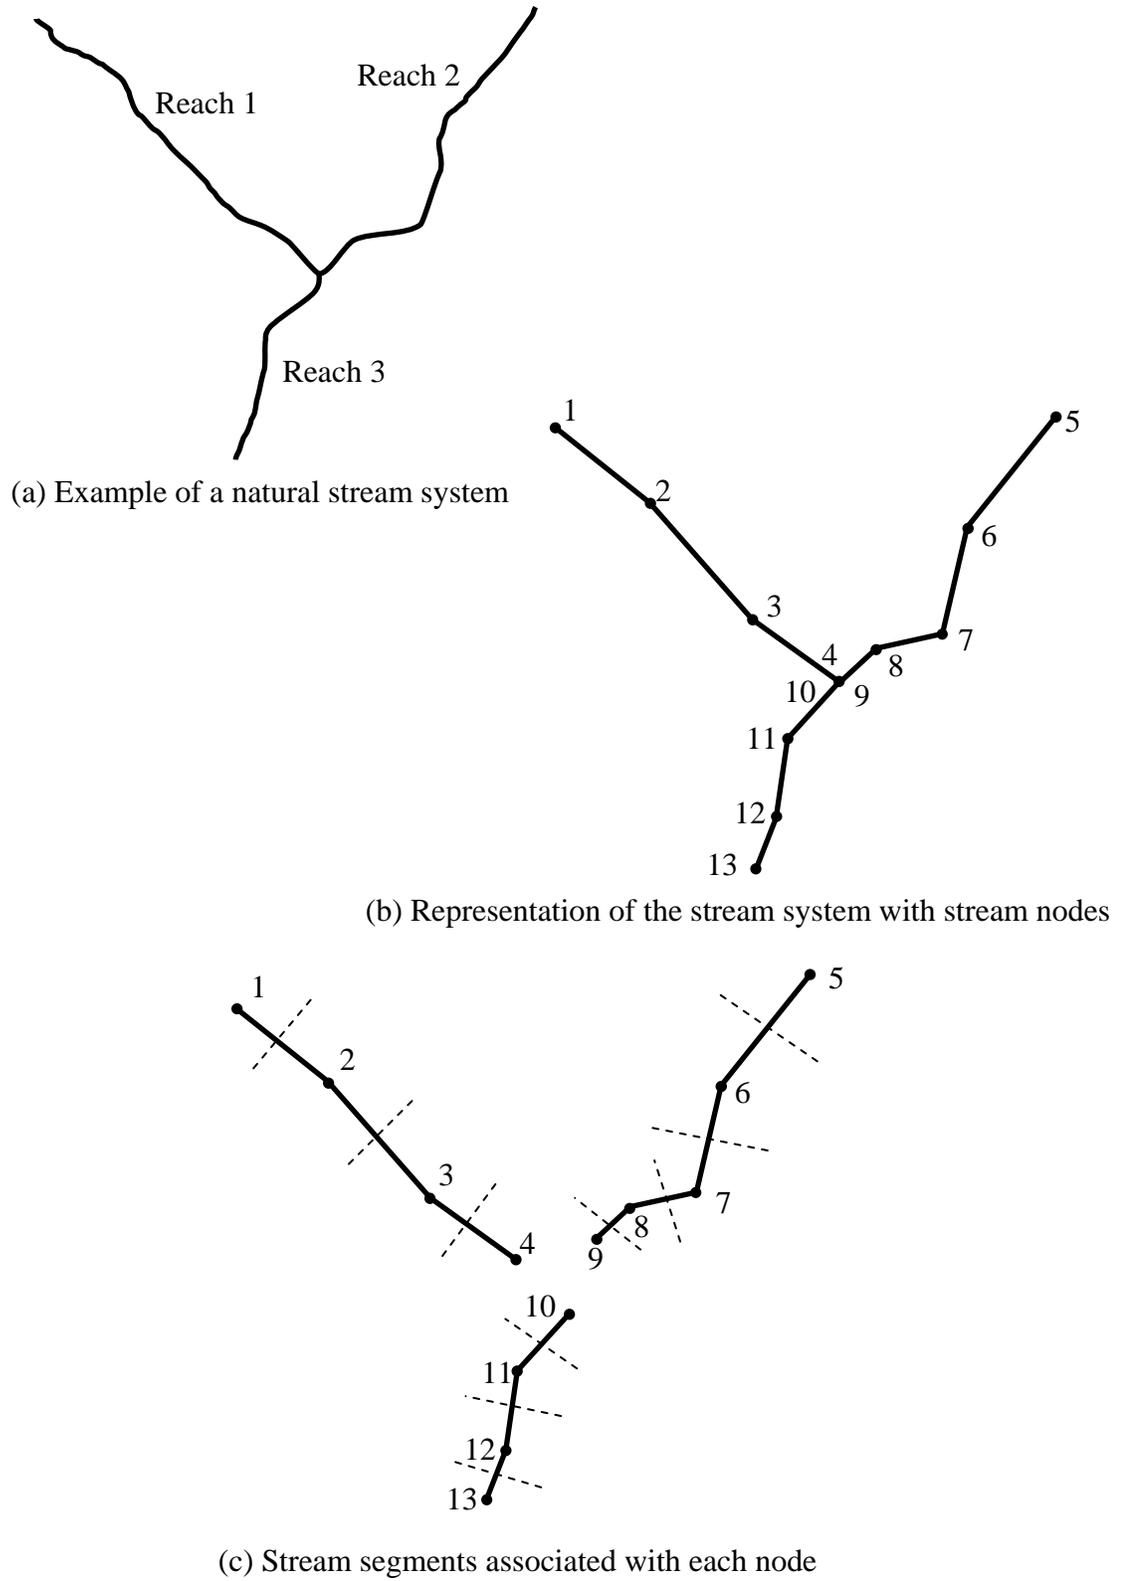

$Q_{s_j}$  = flow from upstream node  $j$ , ( $L^3/T$ );

$R_f$  = surface water return flow from agricultural irrigation and urban water use, ( $L^3/T$ );

$S_r$  = direct runoff due to rainfall excess and subsurface flow that seeps onto the ground surface, ( $L^3/T$ );

$Q_{ws}$  = inflow from the tributaries to the stream node (see small stream boundary conditions), ( $L^3/T$ );

$Q_{brs}$  = inflow from bypasses, ( $L^3/T$ );

**Figure 2.7** Representation of a natural stream system by stream nodes and stream segments in IWFM

- $Q_{td}$  = inflow from tile drains, ( $L^3/T$ );  
 $Q_{lko}$  = inflow due to lake overflow (see the discussion on lakes for the computation of this term), ( $L^3/T$ );  
 $Q_h$  = inflows other than those listed above, ( $L^3/T$ );  
 $Q_b$  = outflow that is diverted as bypass flow, ( $L^3/T$ );  
 $Q_{div}$  = flow that is diverted for agricultural and urban water use, ( $L^3/T$ );  
 $Q_{sint}$  = rate of water exchange between the stream and the groundwater, ( $L^3/T$ );  
 $Q_{s_i}$  = net flow at stream node  $i$  that contributes to the flow at the downstream node, ( $L^3/T$ ).

The number of stream nodes that are considered in the summation term on the right hand side of equation (2.27) depends on the location of the stream node  $i$  (Figure 2.7). If node  $i$  is in the middle of a stream reach, there will be only one upstream node from which flow will be contributing to the flow at node  $i$ . On the other hand, if node  $i$  is located at a confluence, then there will be as many upstream nodes as the number of upstream reaches meeting at the confluence. As an example, consider node 3 of reach 1 in Figure 2.7.c. Writing equation (2.27) for node 3, only node 2 will appear as upstream node. On the other hand, writing equation (2.27) for node 10, nodes 4 and 9 will appear as the upstream nodes.

Substituting equation (2.28) into equation (2.26) and rearranging, one obtains

$$Q_{s_i} - Q_{in} + Q_{bdiv} + Q_{sint} = 0 \quad (2.30)$$

In IWFEM, stream flows are related to stream surface elevations through a rating

curve:

$$Q_{s_i} = Q_{s_i}(h_{s_i}) \quad (2.31)$$

where

$$h_{s_i} = \text{elevation of the stream surface at stream node } i \text{ with respect to a common datum, (L).}$$

### 2.5.1. Diversions and Bypass Flows

In general, diversion rates and bypass flows that occur at a stream node are pre-specified values. In certain occasions bypass flows can also be specified through a rating curve that renders them as a function of the stream flow. If there is enough flow at the stream node so that the total of the diversion and bypass flows can be taken out of the stream, the pre-specified values remain unchanged. If the stream flow is not enough for the required diversion and bypass flows, it is necessary to compute how much of the specified flows can actually be taken out of the stream. To achieve this, it is assumed that diversions occur before the bypass flows. After the diversion flows are taken out of the stream flow, bypass flows are allowed to be taken out of the stream. As such, defining the required diversion and bypass flow rates as  $Q_{\text{divreq}}$  and  $Q_{\text{breq}}$ , respectively, one can compute the actual diversion and bypass flow rates that take place at stream node  $i$  as

$$Q_{\text{div}} = \begin{cases} Q_{\text{divreq}} & \text{if } Q_{\text{in}} \geq Q_{\text{divreq}} \\ Q_{\text{in}} & \text{if } Q_{\text{in}} < Q_{\text{divreq}} \end{cases} \quad (2.32)$$

$$Q_b = \begin{cases} Q_{breq} & \text{if } Q_{s_i}^* \geq Q_{breq} \\ Q_{s_i}^* & \text{if } Q_{s_i}^* < Q_{breq} \end{cases} \quad (2.33)$$

where

$$Q_{s_i}^* = Q_{in} - Q_{div} \quad (2.34)$$

and  $Q_{in}$  is given by equation (2.27). Equations (2.32)-(2.34) reveal that diversions and bypasses are assumed to take place before the stream-groundwater interaction which is detailed in the following section.

### 2.5.2. Stream-Groundwater Interaction

The stream-groundwater interaction is included in IWFM to capture its effect on stream flows and groundwater heads. The exchange of water between the stream and the groundwater along a stream segment can be modeled approximately as (McDonald and Harbaugh, 1988)

$$Q_{sint} = C_{s_i} \left[ \max(h_{s_i}, h_b) - \max(h, h_b) \right] \quad (2.35)$$

where

$Q_{sint}$  = stream-groundwater interaction, ( $L^3/T$ );

$C_{s_i}$  = conductance of the streambed material at stream node  $i$ , ( $L^2/T$ );

$h_{s_i}$  = stream surface elevation, (L);

$h$  = groundwater head at stream node  $i$ , (L);

$h_b$  = elevation of the stream bottom at node  $i$ , (L);

The conductance of the stream bed material that appear in (2.35) can be expressed as

$$C_{s_i} = \frac{K_{s_i}}{d_{s_i}} L_i W_i = \frac{K_{s_i}}{d_{s_i}} A_{s_i} \quad (2.36)$$

where

$K_{s_i}$  = hydraulic conductivity of the stream bed material, (L/T);

$d_{s_i}$  = thickness of the stream bed material, (L);

$L_i$  = length of the stream segment represented by stream node  $i$ , (L);

$W_i$  = wetted perimeter, (L);

$A_{s_i}$  = effective area of the stream segment represented by node  $i$  through which stream-groundwater interaction occurs, (L<sup>2</sup>).

It should be noted that  $Q_{sint}$  and  $A_{s_i}$  that appear in equations (2.35) and (2.36) are the same terms that appear in the groundwater conservation equation (2.15). Stream flow equation (2.30) is coupled with groundwater conservation equation (2.15) through the stream-groundwater interaction term,  $Q_{sint}$ . In order to compute groundwater heads, stream flows and stream-groundwater interaction properly, it is necessary to solve equations (2.15) and (2.30), simultaneously. The solution methodology used in IWFM will be discussed in detail later in this document.

## 2.6. Lakes

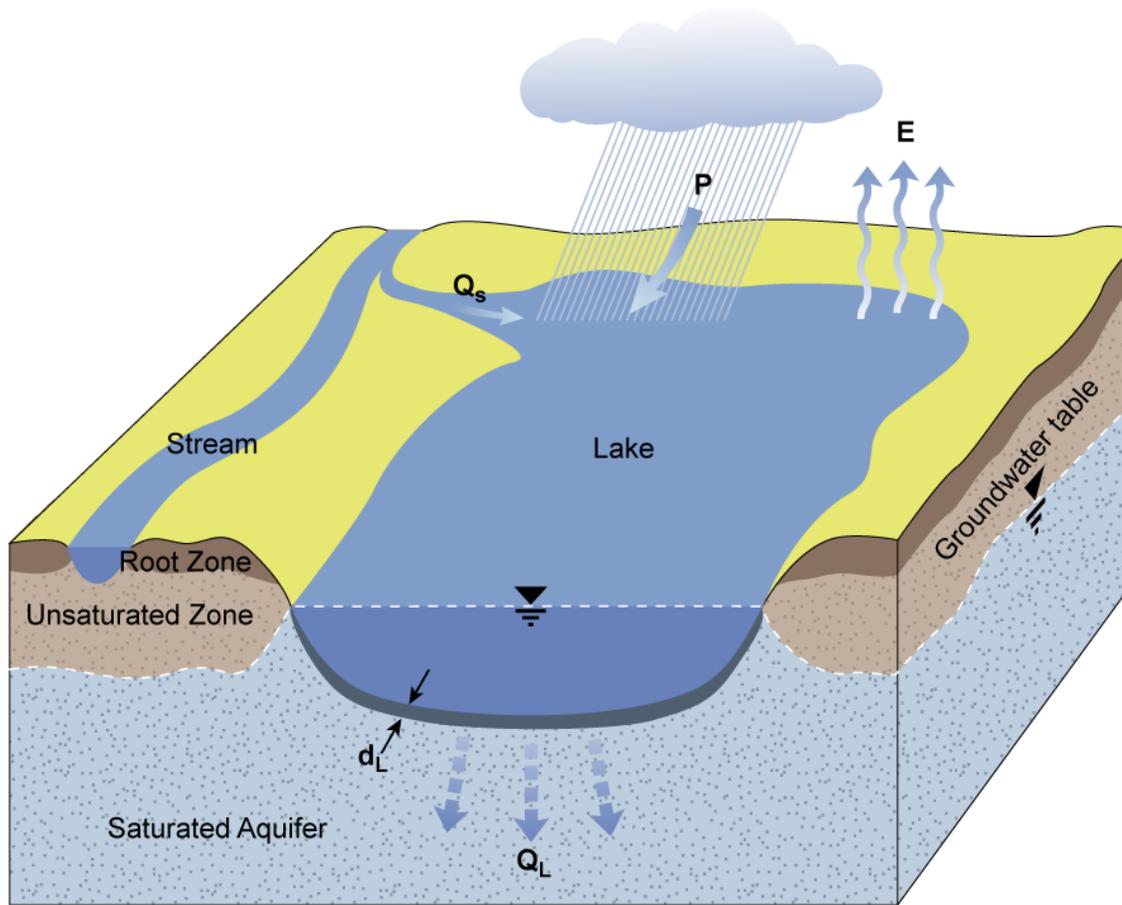

Lakes and similar large water bodies are as important in the hydrological cycle as the groundwater and streams. Lakes interact with groundwater and streams, and can affect the groundwater heads and stream flows drastically. For this reason, the capability of modeling lake storage and its interaction with groundwater and streams has been included in IWFEM. Figure 2.8 shows some of the hydrological components modeled in IWFEM that affect the lake storage.

The conservation equation for lake storage can be expressed as

$$\frac{\partial S_{lk}}{\partial t} - \sum_{i=1}^{N_{lk}} \left( P_{lk_i} A_{lk_i} - EV_{lk_i} A_{lk_i} - Q_{lkint_i} \right) - Q_{brlk} - Q_{inlk} + Q_{lko} = 0 \quad (2.37)$$

where

- $S_{lk}$  = lake storage, ( $L^3$ );
- $i$  = lake node that represents an area of lake, (dimensionless);
- $N_{lk}$  = total number of lake nodes that represent the entire lake area, (dimensionless);
- $P_{lk_i}$  = precipitation onto the lake area represented by node  $i$ , ( $L/T$ );
- $EV_{lk_i}$  = evaporation from the lake area represented by node  $i$ , ( $L/T$ );
- $Q_{lkint_i}$  = lake-groundwater interaction, ( $L^3/T$ );
- $A_{lk_i}$  = lake area represented by node  $i$ , ( $L^2$ );
- $Q_{brlk}$  = inflow from diversion and bypass flows, ( $L^3/T$ );
- $Q_{inlk}$  = inflow from upstream lakes, ( $L^3/T$ );

**LEGEND**

**P**.....Precipitation

**Q<sub>s</sub>**... Streamflow into lake

**E**..... Evaporation

**Q<sub>L</sub>**... Lake-groundwater interaction

**d<sub>L</sub>**.....Thickness of the lake bed

**Figure 2.8** Hydrological components that affect lake storage

$Q_{lko}$  = outflow from lake in case lake surface elevation exceeds a pre-specified maximum elevation, ( $L^3/T$ );

$t$  = time, (T).

As can be seen in equation (2.37), diversion and bypass flows can be set as inflow to the lake. At a lake node  $i$ , evaporation rate is pre-specified as a function of time. Furthermore, lake storage is related to the lake surface elevation through a rating table:

$$S_{lk} = S_{lk}(h_{lk}) \quad ; \quad h_{lk} \leq h_{lk_{max}} \quad (2.38)$$

where

$h_{lk}$  = elevation of lake surface, (L);

$h_{lk_{max}}$  = maximum elevation of lake surface, (L).

If the lake surface elevation exceeds the maximum elevation, the excess water becomes lake outflow,  $Q_{lko}$ . This outflow can be directed into a stream node or into a downstream lake.

### 2.6.1. Lake-Groundwater Interaction

Similar to stream-groundwater interaction, lake-groundwater interaction can be expressed as

$$Q_{lkint_i} = C_{lk_i} \left[ \max(h_{lk}, h_{blk_i}) - \max(h, h_{blk_i}) \right] \quad (2.39)$$

where

$Q_{lkint_i}$  = lake-groundwater interaction, ( $L^3/T$ );

$C_{lk_i}$  = conductance of the lake bed material at lake node  $i$ , ( $L^2/T$ );

- $h_{lk}$  = lake surface elevation, (L);  
 $h$  = groundwater head at lake node  $i$ , (L);  
 $h_{blk_i}$  = elevation of the lake bottom at node  $i$ , (L);

The conductance of the lake bed material that appear in (2.39) can be expressed as

$$C_{lk_i} = \frac{K_{lk_i}}{d_{lk_i}} A_{lk_i} \quad (2.40)$$

where

- $K_{lk_i}$  = hydraulic conductivity of the lake bed material, (L/T);  
 $d_{lk_i}$  = thickness of the lake bed material, (L).

It should be noted that  $Q_{lk_{int_i}}$  and  $A_{lk_i}$  that appear in equations (2.39) and (2.40) are the same terms that appear in the groundwater conservation equation (2.15). Lake storage equation (2.37) is coupled with groundwater conservation equation (2.15) through the lake-groundwater interaction term,  $Q_{lk_{int_i}}$ . In order to compute groundwater heads, lake storage and lake-groundwater interaction properly, it is necessary to solve equations (2.15) and (2.37), simultaneously. The solution methodology used in IWFM will be discussed in detail later in this document.

## 2.7. Land Surface and Root Zone Flow Processes

Precipitation is the natural source for the replenishment of groundwater, stream flows and lake storage. The amount of precipitation that falls directly on the streams and lakes contributes to stream flow and lake storage immediately. Precipitation that falls on

the ground surface infiltrates into the soil at a rate dictated by the type of ground cover, physical characteristics of the soil and the soil moisture content. The portion of the precipitation that is in excess of the infiltration rate generates a surface flow and runs towards nearby streams, lakes or other bodies of water in the direction dictated by the contours of the ground surface. In situations where groundwater table rises high enough and intersects with the ground surface, the groundwater seeps onto the surface contributing to the surface flow generated by the precipitation in excess of infiltration (Dunne, 1978). In IWFEM, the surface flow generated through these means is termed as *direct runoff*. Direct runoff can also infiltrate into the soil further down the slope or evaporate before it even reaches a nearby body of water. However, modeling this complex nature of direct runoff requires highly detailed information on physical characteristics of the soil, ground cover, topography, evaporation patterns, etc. This information is generally not available at the scale that IWFEM is designed for. Therefore, the infiltration and evaporation of direct runoff on its course to a nearby body of water are neglected in IWFEM. Instead, once the direct runoff is computed it is immediately carried to a pre-specified stream location.

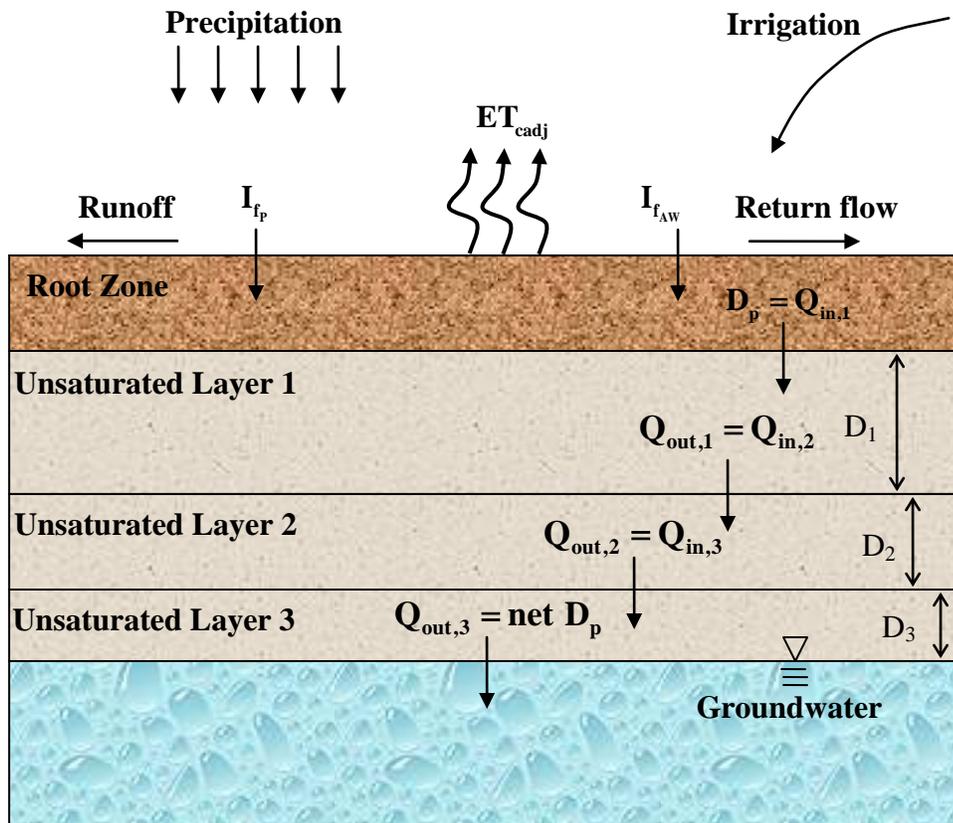

Irrigation of agricultural lands and urban outdoors water use also follow similar infiltration and runoff patterns of precipitation. In IWFEM the surface flows generated by the agricultural irrigation and urban water use is termed as *return flow*. Return flow generated by agricultural irrigation runs in the direction dictated by the contours of the ground surface, whereas return flow generated by the urban water use generally follow man-made structures. In both cases, IWFEM treats return flows similar to the direct runoff and these flows are immediately carried to a pre-specified stream location.

Even though groundwater table can rise and intersect with the ground surface saturating the entire soil profile, an unsaturated zone generally exists between the ground surface and the groundwater table. An unsaturated zone is defined as the soil profile where pore space saturation is less than 100%. The water from precipitation and irrigation water that infiltrate into the soil have to flow through this unsaturated zone before reaching the groundwater as recharge. The top layer of this unsaturated zone designated by the depth of the plant roots through which moisture is drawn out of the soil is called the *root zone*. As moisture in the root zone flows downward due to the gravitational force, it is also drawn out of the soil through plant roots for transpiration and the process of evaporation. The combined processes of plant root uptake for transpiration purposes and evaporation is termed as *evapotranspiration*. Figure 2.10 illustrates an example of a system of root zone and unsaturated zone, and the hydrological processes in these zones as it is modeled in IWFEM.

To connect the groundwater system with the surface flow processes, simulation of storage and flow through the root zone and unsaturated zone is necessary. In general, moisture in the root and unsaturated zones can move in horizontal direction as well as the vertical direction. In IWFEM, it is assumed that the horizontal movement of the moisture in the root and unsaturated zones is negligible compared to the vertical movement, therefore only the flow of the moisture in the vertical direction is addressed. To increase the accuracy of the simulated vertical flow, IWFEM has the functionality to separate the unsaturated zone into multiple layers (Figure 2.10). The moisture that leaves the root zone and enters the unsaturated zone is termed as *deep percolation*. The moisture travels

downward through the unsaturated zone and eventually recharges the groundwater. The groundwater recharge is named as *net deep percolation* (Figure 2.10).

The methods that are used to simulate land surface and root zone processes in IWFMs are discussed in detail in a separate document (see DWR, 2012) and will not be discussed any further here. DWR (2012) details the IWFM Demand Calculator (IDC) which is also used as the root zone and land surface flow simulation component in IWFMs.

**Figure 2.9** Schematic representation of flow through the root zone and the unsaturated zone

## 2.8. Moisture Routing in the Unsaturated Zone

Moisture routing in the unsaturated zone is performed over a pre-specified number of unsaturated layers. The simulation of moisture through multiple layers approximates the vertical movement of water in the physical system more precisely because of the finer spatial discretization created. The lag between the time when moisture enters the unsaturated zone above and the time it leaves the unsaturated zone below can be simulated more accurately.

The methodology for routing moisture through unsaturated layers is similar to that used in the root zone as described by DWR (2012). The conservation equation for an unsaturated layer  $m$  is

$$\frac{\partial(D_n \theta_{u,n})}{\partial t} = Q_{in,n} - Q_{out,n} \quad (2.41)$$

where

- $n$  = unsaturated layer number counting from top down, (dimensionless);
- $D_n$  = thickness of layer  $n$ , (L);
- $\theta_{u,n}$  = soil moisture in  $n^{\text{th}}$  unsaturated layer, (L/L);
- $Q_{in,n}$  = inflow into unsaturated layer  $n$  from layer  $n-1$ , (L/T);
- $Q_{out,n}$  = outflow from unsaturated layer  $n$  to layer  $n+1$ , (L/T);
- $t$  = time, (T).

Assuming that the vertical head gradient is unity, using van Genuchten-Mualem equation (Mualem, 1976; van Genuchten, 1980) and assuming residual moisture content is negligible, the flow out of layer n,  $Q_{out,n}$ , can be expressed as

$$Q_{out,n} = K_{u,n} \quad (2.42)$$

and

$$K_{u,n} = K_{s,n} \left( \frac{\theta_{u,n}}{\eta_{T,n}} \right)^{1/2} \left\{ 1 - \left[ 1 - \left( \frac{\theta_{u,n}}{\eta_{T,n}} \right)^{1/m} \right]^m \right\}^2 \quad (2.43)$$

$$m = \frac{\lambda_n}{\lambda_n + 1} \quad (2.44)$$

where

$K_{u,n}$  = unsaturated hydraulic conductivity of layer n, (L/T);

$K_{s,n}$  = saturated hydraulic conductivity of layer n, (L/T);

$\eta_{T,n}$  = total porosity of unsaturated layer n, (L/L);

$\lambda_n$  = pore size distribution index of unsaturated layer n, (dimensionless).

As an alternative to the van Genuchten-Mualem equation, IWFM can use Campbell's approach (Campbell, 1974) to represent the unsaturated hydraulic conductivity:

$$K_{u,n} = K_{s,n} \left( \frac{\theta_{u,n}}{\eta_{T,n}} \right)^{3 + \frac{2}{\lambda_n}} \quad (2.45)$$

where the assumption of negligible residual moisture content is applied.

Equation (2.41), coupled with (2.42), is solved for each unsaturated layer from top down in a sequential order. At each layer, the inflow term  $Q_{in,n}$  is known from the routing of moisture at the layer above, i.e.  $Q_{in,n} = Q_{out,n-1}$ . For the first unsaturated layer (i.e.  $n = 1$ ),  $Q_{in,n}$  is equal to the deep percolation computed by the root zone component of IWFM (DWR, 2012). The outflow at the last unsaturated layer is the net deep percolation into the groundwater system.

The number of layers and their thicknesses are predefined input parameters. Based on the elevation of the groundwater table, three scenarios can occur for an unsaturated layer during the simulation period: (i) the total thickness of the layer is unsaturated; (ii) the groundwater table intersects the unsaturated layer so that the partial thickness of the layer is saturated and (iii) the layer is occupied completely by groundwater, and is no longer unsaturated. If the elevation of the groundwater table is lower than the bottom of the last unsaturated layer, then IWFM re-computes the thickness of the last layer and extends it down to the groundwater table. If a layer becomes fully saturated during the simulation period due to the rising groundwater table, the moisture routing in that unsaturated layer is ceased until the layer is at least partially unsaturated again. If a layer is partially occupied by saturated groundwater, then the thickness of the layer,  $D_{u,n}$ , that appears in equation (2.41) is computed as the unsaturated thickness of that layer. Therefore, even though the thicknesses of each unsaturated layer are pre-specified, they are in fact dynamic, and computed internally in IWFM through the simulation period.

## 2.9. Small Watersheds

Small watersheds adjacent to a model area can contribute to surface and subsurface flows occurring in the model area. To account for the flow contributions of small watersheds, surface and subsurface flows at these watersheds are simulated with an approximate method. It is assumed that flow between the small watersheds and the modeled region is one-way; the direction of subsurface and surface flows is always from small watersheds into the modeled region.

The surface flow that occurs in a small watershed is assumed to be due solely to the direct runoff of precipitation:

$$S_{wr} = \frac{1}{\Delta t} \frac{(P_w \Delta t - 0.2S_w)^2}{P_w \Delta t + 0.8S_w} A_w \quad (2.46)$$

where

$S_{wr}$  = direct runoff from the small watershed, ( $L^3/T$ );

$P_w$  = precipitation rate at the small watershed, ( $L/T$ );

$S_w$  = retention parameter at small watershed modified with respect to the soil moisture in the unsaturated zone (see previous sections for the computation of this term), ( $L$ );

$\Delta t$  = time period over which the precipitation rate has occurred, ( $T$ );

$A_w$  = surface area of the small watershed, ( $L^2$ ).

As described earlier, once the direct runoff is computed the infiltration that occurs at the small watershed can be computed as

$$I_{wfp} = (P_w - S_{wr}) A_w \quad (2.47)$$

where

$$I_{wf,p} = \text{infiltration of precipitation at the small watershed, (L}^3\text{/T).}$$

The vertical movement of moisture in the unsaturated zone at the small watershed is computed using the methods described in preceding sections and in DWR (2012). The computed deep percolation, as an outcome of the soil moisture accounting, represents the inflow to the groundwater storage at a small watershed. The conservation equation for the groundwater storage at the small watershed is expressed as

$$\frac{\partial S_{wg}}{\partial t} = D_{wp} - Q_{wg} - Q_{wgs} \quad (2.48)$$

where

$$S_{wg} = \text{groundwater storage within the small watershed boundary, (L}^3\text{);}$$

$$D_{wp} = \text{net deep percolation, i.e. recharge, to the groundwater storage within the small watershed domain (computed using the methods described in the preceding section), (L}^3\text{/T);}$$

$$Q_{wg} = \text{subsurface outflow from the small watershed that contributes to the groundwater storage at the modeled area, (L}^3\text{/T);}$$

$$Q_{wgs} = \text{contribution of groundwater storage to the surface flow at the small watershed, (L}^3\text{/T);}$$

$$t = \text{time, (T).}$$

The subsurface flow from the small watershed,  $Q_{wg}$ , contributes to the groundwater storage at the modeled area at pre-specified locations. It is approximated as

$$Q_{wg} = C_{wg} S_{wg} \quad (2.49)$$

where

$C_{wg}$  = subsurface flow recession coefficient, (1/T).

Contribution of the groundwater storage to the surface flow at the small watershed,  $Q_{wgs}$ , is computed as a non-zero value only if the groundwater storage,  $S_{wg}$ , exceeds a predefined threshold value:

$$Q_{wgs} = C_{ws} (S_{wg} - S_{wgt}) \quad (2.50)$$

where

$C_{ws}$  = surface runoff recession coefficient, (1/T);

$S_{wgt}$  = threshold value for groundwater storage within the small watershed above which groundwater at the small watershed contributes to surface flow, ( $L^3$ ).

Finally, the total surface flow from the small watershed that contributes to the surface flows at predefined locations in the modeled area is computed as

$$Q_{ws} = Q_{wgs} + S_{wr} \quad (2.51)$$

where

$Q_{ws}$  = total surface flow from the small watershed that contributes to the surface flows in the modeled area, ( $L^3/T$ ).

### 3. Numerical Methods Used in Modeling of Hydrological Processes

The conservation equations for the hydrological processes modeled in IWFM are detailed in previous chapter. In order to model the hydrological processes and the interactions among them, it is necessary to solve these equations simultaneously. However, since most of these equations are non-linear and the interaction terms are complex, it is impossible to obtain an analytical solution except for very simple, hypothetical cases. For this reason, IWFM utilizes numerical techniques to obtain approximate solutions to the equations listed in the previous chapter. This chapter is devoted to the explanation of the numerical methods used in IWFM.

#### 3.1. Finite Element Representation of the Groundwater Equation

The conservation equation for the groundwater system is given in the previous chapter as

$$\begin{aligned} 0 = & \frac{\partial S_s h}{\partial t} - \bar{\nabla} \cdot (\mathbf{T} \bar{\nabla} h) + I_u L_u \Delta h^u + I_d L_d \Delta h^d - q_o + q_{sd} \\ & - \delta(x - x_s, y - y_s) \frac{Q_{sint}}{A_s} \\ & - \delta(x - x_{lk}, y - y_{lk}) \frac{Q_{lkint}}{A_{lk}} \\ & - \delta(x - x_{td}, y - y_{td}) \frac{Q_{td}}{A_{td}} \end{aligned} \quad (3.1)$$

Equation (3.1) is a partial differential equation that models the unsteady groundwater head field in a multi-layer aquifer system that consists of confined and/or unconfined layers. In order to solve this equation, IWFM utilizes the Galerkin finite

element method to discretize the spatial domain and obtain a set of ordinary differential equations in which the unknowns are the groundwater heads at a finite number of nodal points within the model domain. The spatially and temporally continuous groundwater head field in an aquifer layer  $m$ , can be approximated by the head values at discrete nodal points as (Huyakorn and Pinder, 1983):

$$\hat{h}(x, y, t) = \sum_{j=N \cdot (m-1) + 1}^{N \cdot m} \omega_j(x, y) h_j(t) \quad (3.2)$$

where

$\hat{h}(x, y, t)$  = approximation of  $h(x, y, t)$ , (L);

$\omega_j(x, y)$  = shape functions, (dimensionless);

$h_j(t)$  = nodal hydraulic head values, (L);

$m$  = aquifer layer number, (dimensionless);

$N$  = total number of nodal points in an aquifer layer, (dimensionless).

Equation (3.2) is valid for all layers of an aquifer system that consists of  $N_L$  layers. Substitution of (3.2) into (3.1) will generally result in a nonzero residual  $\varepsilon$ :

$$\begin{aligned} \varepsilon = & \frac{\partial S_s \hat{h}}{\partial t} - \bar{\nabla} \cdot (\mathbf{T} \bar{\nabla} \hat{h}) + I_u L_u \Delta \hat{h}^u + I_d L_d \Delta \hat{h}^d - q_o + q_{sd} \\ & - \delta(x - x_s, y - y_s) \frac{Q_{sint}}{A_s} \\ & - \delta(x - x_{lk}, y - y_{lk}) \frac{Q_{lkint}}{A_{lk}} \\ & - \delta(x - x_{td}, y - y_{td}) \frac{Q_{td}}{A_{td}} \end{aligned} \quad (3.3)$$

According to the Galerkin approach, the inner products of equation (3.3) and the shape functions  $\omega_i$  are required to be equal to zero. That is, equation (3.3) is multiplied by

the shape functions  $\omega_i$  ( $i = N \cdot (m-1) + 1, \dots, N \cdot m$ ) for each aquifer layer. The resulting  $N \times N_L$  equations are integrated over the entire domain and the result of each of these integrals is required to be equal to zero (Huyakorn and Pinder, 1983):

$$\begin{aligned}
0 = \iint_{\Omega} & \left( \frac{\partial S_s \hat{h}}{\partial t} - \bar{\nabla} \cdot (\mathbf{T} \bar{\nabla} \hat{h}) + I_u L_u \Delta \hat{h}^u + I_d L_d \Delta \hat{h}^d - q_o + q_{sd} \right. \\
& - \delta(x - x_s, y - y_s) \frac{Q_{sint}}{A_s} \\
& - \delta(x - x_{lk}, y - y_{lk}) \frac{Q_{lkint}}{A_{lk}} \\
& \left. - \delta(x - x_{td}, y - y_{td}) \frac{Q_{td}}{A_{td}} \right) \omega_i d\Omega \quad \begin{array}{l} i = N \cdot (m-1) + 1, \dots, N \cdot m \\ m = 1, \dots, N_L \end{array} \quad (3.4)
\end{aligned}$$

where

$\Omega$  = spatial domain of the problem.

It should be noted that the shape functions depend only on the geometric characteristics of the finite elements, therefore they are the same for each layer, i.e.

$\omega_i = \omega_{i+N} = \dots = \omega_{i+N \cdot (N_L-1)}$  where  $i = 1, \dots, N$ .

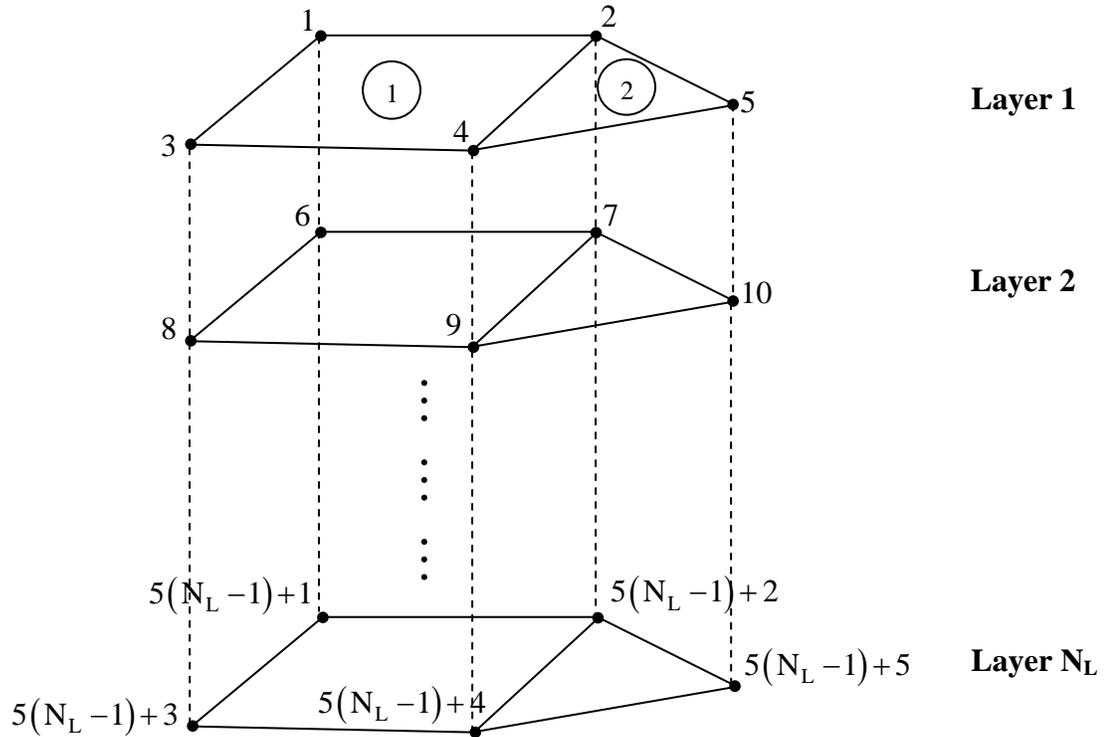

Equation (3.4) is valid for all layers of a multi-layer aquifer system with  $N_L$  layers. In fact it is necessary to define equation (3.4) for all layers of the aquifer system in order to obtain a closed system of equations. Figure 3.1 depicts the node numbering convention used in IWFM for a hypothetical aquifer system with  $N_L$  layers and each layer discretized into 2 elements with  $N=5$  nodes. This node numbering convention is used interchangeably in the rest of this document to express  $L_u$ ,  $L_d$ ,  $h_u$  and  $h_d$  (refer to previous chapter for a definition of the terms) for a node as  $L_{j-N}$ ,  $L_{j+N}$ ,  $h_{j-N}$  and  $h_{j+N}$ , respectively.

Substituting equation (3.2) into (3.4) and applying Green's theorem to eliminate the second order derivatives result in the following equation:

$$\begin{aligned}
0 = & \iint_{\Omega} \sum_{j=N \cdot (m-1)+1}^{N \cdot m} \frac{\partial S_{s_j} h_j}{\partial t} \omega_i \omega_j d\Omega \\
& - \iint_{\Gamma} \sum_{j=N \cdot (m-1)+1}^{N \cdot m} T \omega_i \bar{\nabla} (h_j \omega_j) \cdot \bar{n} d\Gamma + \iint_{\Omega} \sum_{j=N \cdot (m-1)+1}^{N \cdot m} T \bar{\nabla} (h_j \omega_j) \cdot \bar{\nabla} \omega_i d\Omega \\
& + H(m-2) \iint_{\Omega} \sum_{j=N \cdot (m-1)+1}^{N \cdot m} L_{j-N} \Delta h_j^u \omega_i \omega_j d\Omega \\
& + [1 - H(m - N_L)] \iint_{\Omega} \sum_{j=N \cdot (m-1)+1}^{N \cdot m} L_{j+N} \Delta h_j^d \omega_i \omega_j d\Omega \\
& - \iint_{\Omega} q_o \omega_i d\Omega + \iint_{\Omega} q_{sd} \omega_i d\Omega \\
& - \iint_{\Omega} \delta(x - x_s, y - y_s) \frac{Q_{sint}}{A_s} \omega_i d\Omega \\
& - \iint_{\Omega} \delta(x - x_{lk}, y - y_{lk}) \frac{Q_{lkint}}{A_{lk}} \omega_i d\Omega \\
& - \iint_{\Omega} \delta(x - x_{td}, y - y_{td}) \frac{Q_{td}}{A_{td}} \omega_i d\Omega \quad \begin{array}{l} i = N \cdot (m-1) + 1, \dots, N \cdot m \\ m = 1, \dots, N_L \end{array} \quad (3.5)
\end{aligned}$$

where

- $\Gamma$  = boundary of the spatial domain, (L);
- $\bar{n}$  = outward unit vector perpendicular to the boundary, (dimensionless);
- $N_L$  = total number of aquifer layers, (dimensionless);

**Figure 3.1** Node numbering convention used in IWFEM for an aquifer system with  $N_L$  layers and  $N=5$  nodes in each layer

$H(\bullet)$  = Heaviside (step) function to express the indicator functions  $I_u$  and  $I_d$  in terms of the layer number  $m$ , explicitly, (dimensionless);

The vertical head differences,  $\Delta h_j^u$  and  $\Delta h_j^d$ , at a finite element node are also introduced in (3.5). These terms are computed by using the head values in the vertical direction at a finite element node; i.e.  $h_{j-N}$ ,  $h_j$  and  $h_{j+N}$ .

IWFEM utilizes a mass lumping method to simplify equation (3.5). According to this method, it is assumed that the head over an element can be approximated by a head value at any one of the nodes; i. e.  $\hat{h} = h_j$ . The choice of the node for this purpose is

based solely on the index  $j$ . It has been suggested, particularly in non-linear equations, that mass lumping typically generates a smoother numerical solution than that arising from the strict Galerkin, or *consistent*, formulation (Allen, et al., 1988). Applying the mass lumping technique to the storage and leakage terms of (3.5) (i.e. first, fourth and fifth integral terms), and performing the differentiations in the third integral term results in

$$\begin{aligned}
0 = & \iint_{\Omega} \frac{\partial S_{s_i} h_i}{\partial t} \omega_i d\Omega \\
& - \iint_{\Gamma} q_{\Gamma} \omega_i d\Gamma + \sum_{j=N \cdot (m-1)+1}^{N \cdot m} \iint_{\Omega} Th_j \left( \frac{\partial \omega_i}{\partial x} \frac{\partial \omega_j}{\partial x} + \frac{\partial \omega_i}{\partial y} \frac{\partial \omega_j}{\partial y} \right) d\Omega \\
& + H(m-2) \iint_{\Omega} L_{i-N} \Delta h_i^u \omega_i d\Omega \\
& + [1 - H(m - N_L)] \iint_{\Omega} L_{i+N} \Delta h_i^d \omega_i d\Omega \\
& - \iint_{\Omega} q_o \omega_i d\Omega + \iint_{\Omega} q_{sd} \omega_i d\Omega \\
& - \iint_{\Omega} \delta(x - x_s, y - y_s) \frac{Q_{sint}}{A_s} \omega_i d\Omega \\
& - \iint_{\Omega} \delta(x - x_{lk}, y - y_{lk}) \frac{Q_{lkint}}{A_{lk}} \omega_i d\Omega \\
& - \iint_{\Omega} \delta(x - x_{td}, y - y_{td}) \frac{Q_{td}}{A_{td}} \omega_i d\Omega \quad \begin{array}{l} i = N \cdot (m-1) + 1, \dots, N \cdot m \\ m = 1, \dots, N_L \end{array} \quad (3.6)
\end{aligned}$$

where  $q_{\Gamma} = \sum_{j=N \cdot (m-1)+1}^{N \cdot m} T \bar{\nabla}(h_j \omega_j) \cdot \bar{n}$  is the inflow that is perpendicular to the boundary of aquifer layer  $m$ . Equation (3.6) is valid for all layers of a multi-layer aquifer system. Therefore, it represents a set of  $N \times N_L$  ordinary differential equations for an aquifer system that is comprised of  $N_L$  layers with the unknown groundwater head values at  $N \times N_L$  nodal points.

To solve equation (3.6), the time coordinate is also discretized using the fully implicit discretization method. Utilization of this method results in the following equation:

$$\begin{aligned}
0 = & \iint_{\Omega} \frac{S_{s_i}^{t+1} (h_i^{t+1} - \text{TOP}_i) + S_{s_i}^t (\text{TOP}_i - h_i^t)}{\Delta t} \omega_i d\Omega \\
& - \iint_{\Gamma} q_{\Gamma}^{t+1} \omega_i d\Gamma + \sum_{j=N \cdot (m-1)+1}^{N \cdot m} \iint_{\Omega} T^{t+1} h_j^{t+1} \left( \frac{\partial \omega_i}{\partial x} \frac{\partial \omega_j}{\partial x} + \frac{\partial \omega_i}{\partial y} \frac{\partial \omega_j}{\partial y} \right) d\Omega \\
& + H(m-2) \iint_{\Omega} L_{i-N} (\Delta h_i^u)^{t+1} \omega_i d\Omega \\
& + [1 - H(m - N_L)] \iint_{\Omega} L_{i+N} (\Delta h_i^d)^{t+1} \omega_i d\Omega \\
& - \iint_{\Omega} q_o^{t+1} \omega_i d\Omega + \iint_{\Omega} q_{sd}^{t+1} \omega_i d\Omega \\
& - \iint_{\Omega} \delta(x - x_s, y - y_s) \frac{Q_{sint}^{t+1}}{A_s} \omega_i d\Omega \\
& - \iint_{\Omega} \delta(x - x_{lk}, y - y_{lk}) \frac{Q_{lkint}^{t+1}}{A_{lk}} \omega_i d\Omega \\
& - \iint_{\Omega} \delta(x - x_{td}, y - y_{td}) \frac{Q_{td}^{t+1}}{A_{td}} \omega_i d\Omega \quad \begin{array}{l} i = N \cdot (m-1) + 1, \dots, N \cdot m \\ m = 1, \dots, N_L \end{array} \quad (3.7)
\end{aligned}$$

where

$\text{TOP}_i$  = top elevation of the aquifer at node  $i$ , (L);

$\Delta t$  = length of time step, (T);

$t$  = index for time step, (dimensionless).

The time discretization of the first integral term in (3.7) reflects the effort to simulate changing aquifer conditions. As an example, consider the case where the

aquifer converts from confined to unconfined during a simulation period  $\Delta t$ . At time step  $t$ ,  $S_{s_i}^t$  is equal to the storage coefficient,  $S_{o_i}$ , of the confined aquifer. At time step  $t+1$ ,  $S_{s_i}^{t+1}$  is equal to the specific yield,  $S_{y_i}$ , of the unconfined aquifer. In this case, the rate of release of water from storage during the time step has two components (McDonald and Harbaugh, 1988):

$$\frac{S_{o_i} (TOP_i - h_i^t)}{\Delta t} \quad (3.8)$$

and

$$\frac{S_{y_i} (h_i^{t+1} - TOP_i)}{\Delta t} \quad (3.9)$$

Equation (3.8) is the rate of release of water from the confined storage and equation (3.9) is the rate of release of water from the unconfined storage.

To compute the integrals in (3.7), it is necessary to define the global shape functions,  $\omega_i$ , explicitly. In finite element method, the shape functions are defined separately for each element so that an *element shape function*,  $\omega_i^e$ , is non-zero only over the particular element it is defined for, and is zero for the rest of the spatial domain. When the element shape functions are combined, they will produce the global shape functions within the model domain. Since element shape functions are non-zero only over the particular element, the integrals in (3.7) defined over the entire domain,  $\Omega$ , will reduce to integrals over the part of the domain occupied by individual elements,  $\Omega^e$ . With this approach, the task is reduced to the computation of the contribution of each

element to the global set of equations given in (3.7). Based on the above discussion, (3.7)

can be expressed as

$$\begin{aligned}
0 = & \sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} \left\{ \iint_{\Omega^e} \frac{S_{s_i}^{t+1} (h_i^{t+1} - \text{TOP}_i) + S_{s_i}^t (\text{TOP}_i - h_i^t)}{\Delta t} \omega_i^e d\Omega^e \right. \\
& - \iint_{\Gamma^e} q_{\Gamma^e}^{t+1} \omega_i^e d\Gamma^e + \sum_{j=N \cdot (m-1)+1}^{N \cdot m} \iint_{\Omega^e} (T^e)^{t+1} h_j^{t+1} \left( \frac{\partial \omega_i^e}{\partial x} \frac{\partial \omega_j^e}{\partial x} + \frac{\partial \omega_i^e}{\partial y} \frac{\partial \omega_j^e}{\partial y} \right) d\Omega^e \\
& + H(m-2) \iint_{\Omega^e} L_{i-N} (\Delta h_i^u)^{t+1} \omega_i^e d\Omega^e \\
& + [1 - H(m - N_L)] \iint_{\Omega^e} L_{i+N} (\Delta h_i^d)^{t+1} \omega_i^e d\Omega^e \\
& - \iint_{\Omega^e} q_{o_i}^{t+1} \omega_i^e d\Omega^e + \iint_{\Omega^e} q_{sd}^{t+1} \omega_i^e d\Omega^e \\
& - \iint_{\Omega^e} \delta(x - x_s, y - y_s) \frac{Q_{sint}^{t+1}}{A_s} \omega_i^e d\Omega^e \\
& - \iint_{\Omega^e} \delta(x - x_{lk}, y - y_{lk}) \frac{Q_{lkint}^{t+1}}{A_{lk}} \omega_i^e d\Omega^e \\
& \left. - \iint_{\Omega^e} \delta(x - x_{td}, y - y_{td}) \frac{Q_{td}^{t+1}}{A_{td}} \omega_i^e d\Omega^e \right\} \begin{cases} i = N \cdot (m-1) + 1, \dots, N \cdot m \\ m = 1, \dots, N_L \end{cases} \quad (3.10)
\end{aligned}$$

where

- $\omega_i^e$  = element shape function defined at node  $i$  of element  $e$ ,  
(dimensionless);
- $\Omega^e$  = portion of the model domain occupied by element  $e$ , ( $L^2$ );
- $\Gamma^e$  = face of element  $e$  that lies on the model boundary, ( $L$ );
- $e$  = index for element number, (dimensionless);
- $N_e$  = number of elements in an aquifer layer, (dimensionless).

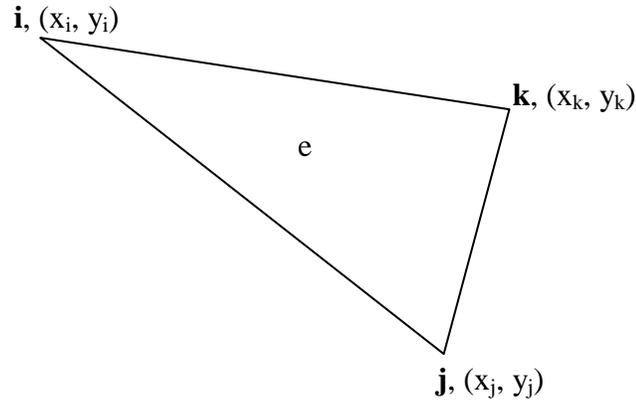

A particular equation from the equation set (3.10) represents the approximate form of the groundwater conservation equation at a node  $i$ . The element shape functions will be non-zero only for those elements that connect at node  $i$ . Therefore, only the integrals of (3.10) that are defined over these elements will have non-zero values.

In IWFEM, the finite element method is implemented with linear triangular and/or bilinear quadrilateral elements. In this approach, three nodes define a triangular element, whereas a quadrilateral element consists of four nodes. For both types of elements, the nodes are the points within the problem domain where heads are calculated. In the following section, the expressions of the element shape functions for linear triangular and bilinear quadrilateral elements are derived.

### **3.1.1. Shape Functions**

#### ***3.1.1.a. Linear Triangular Elements***

For a linear triangular element with nodes  $i, j, k$  in the counterclockwise direction (Figure 3.2), the head over the element  $e$  can be approximated by a linear interpolation function (Huyakorn and Pinder, 1983):

**Figure 3.2** A representative triangular element

$$\hat{h}^e(x, y) = a_1 + a_2x + a_3y \quad (3.11)$$

Substituting the coordinates and the head values at each node into (3.11) will generate 3 equations with 3 unknowns, namely  $a_1$ ,  $a_2$  and  $a_3$ . Solving the system of equations and rearranging terms results in an estimate of the head that is valid over the linear triangular element  $e$ :

$$\hat{h}^e(x, y) = \omega_i^e(x, y)h_i + \omega_j^e(x, y)h_j + \omega_k^e(x, y)h_k \quad (3.12)$$

where

$$\omega_i^e(x, y) = \frac{1}{2A^e} [(x_j y_k - x_k y_j) + (y_j - y_k)x + (x_k - x_j)y] \quad (3.13)$$

$$\omega_j^e(x, y) = \frac{1}{2A^e} [(x_k y_i - x_i y_k) + (y_k - y_i)x + (x_i - x_k)y] \quad (3.14)$$

$$\omega_k^e(x, y) = \frac{1}{2A^e} [(x_i y_j - x_j y_i) + (y_i - y_j)x + (x_j - x_i)y] \quad (3.15)$$

$$\begin{aligned}
A^e &= \frac{1}{2} \left[ (x_i y_j - x_j y_i) + (x_k y_i - x_i y_k) + (x_j y_k - x_k y_j) \right] \\
&= \frac{1}{2} \left[ (x_i - x_k)(y_j - y_k) + (x_j - x_k)(y_k - y_i) \right]
\end{aligned} \tag{3.16}$$

In (3.12),  $\omega_i^e, \omega_j^e, \omega_k^e$  are the element shape functions and  $A^e$  is the area of the triangular element.

### 3.1.1.b. *Bilinear Quadrilateral Elements*

To define the shape functions for bilinear quadrilateral elements, the element coordinates are transformed from  $(x, y)$  space into  $(\xi, \eta)$  space (see Figure 3.3) so as to use efficient numerical techniques in carrying out the integrals given in equation (3.10). Using the Lagrange polynomials,  $x$  and  $y$  can be expressed in terms of  $\xi$  and  $\eta$  in the following form (Huyakorn and Pinder, 1983):

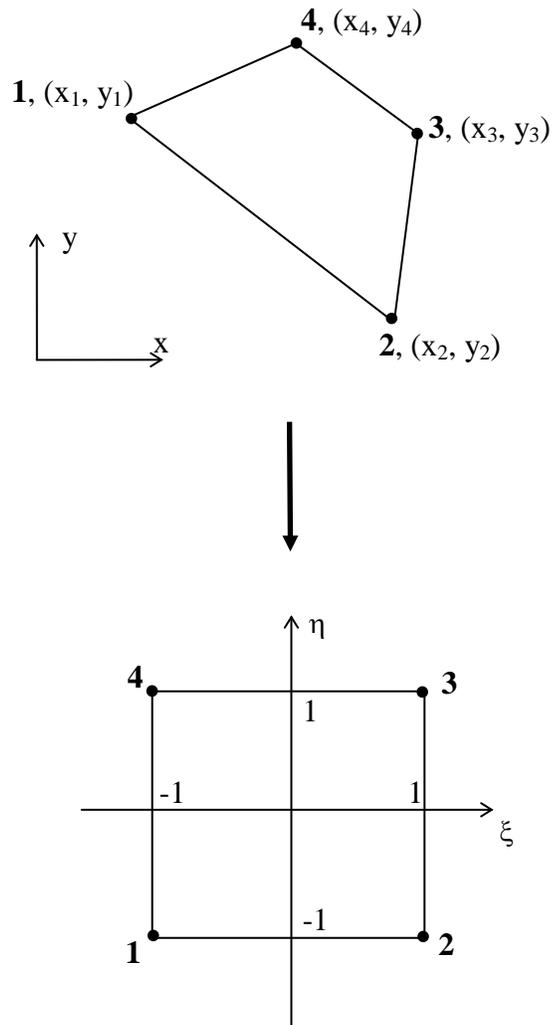

$$x = \sum_{m=1}^4 \omega_m^e(\xi, \eta) x_m \tag{3.17}$$

$$y = \sum_{m=1}^4 \omega_m^e(\xi, \eta) y_m \tag{3.18}$$

where  $\omega_m^e(\xi, \eta)$  are the element shape functions in  $(\xi, \eta)$  space.

The shape functions  $\omega_m^e(\xi, \eta)$  can be expressed in terms of first-degree Lagrange polynomials as

$$\omega_m^e(\xi, \eta) = \prod_{\substack{i=1 \\ \xi_i \neq \xi^m}}^2 \left( \frac{\xi - \xi_i}{\xi^m - \xi_i} \right) \prod_{\substack{k=1 \\ \eta_k \neq \eta^m}}^2 \left( \frac{\eta - \eta_k}{\eta^m - \eta_k} \right), \quad m = 1, \dots, 4 \tag{3.19}$$

**Figure 3.3** Transformation of a quadrilateral element from  $(x, y)$  space to  $(\xi, \eta)$  space

where  $\xi^m$  and  $\eta^m$  are the coordinate values of node  $m$  in  $(\xi, \eta)$  space, whereas  $\xi_1 = \eta_1 = -1$  and  $\xi_2 = \eta_2 = 1$ . The formulation in (3.19) results in the following shape functions:

$$\omega_1^e(\xi, \eta) = \frac{1}{4}(\xi - 1)(\eta - 1) \quad (3.20)$$

$$\omega_2^e(\xi, \eta) = \frac{1}{4}(1 + \xi)(1 - \eta) \quad (3.21)$$

$$\omega_3^e(\xi, \eta) = \frac{1}{4}(\xi + 1)(\eta + 1) \quad (3.22)$$

$$\omega_4^e(\xi, \eta) = \frac{1}{4}(1 - \xi)(1 + \eta) \quad (3.23)$$

Furthermore, an integral defined over the element area in  $(x, y)$  space can be expressed in  $(\xi, \eta)$  space as

$$\int_{y_a}^{y_b} \int_{x_a}^{x_b} f(x, y) dx dy = \int_{-1}^1 \int_{-1}^1 f(\xi, \eta) |J| d\xi d\eta \quad (3.24)$$

where  $|J|$  is the determinant of the Jacobian of the transformation from  $(x, y)$  space into  $(\xi, \eta)$  space:

$$|J| = \begin{vmatrix} \frac{\partial x}{\partial \xi} & \frac{\partial y}{\partial \xi} \\ \frac{\partial x}{\partial \eta} & \frac{\partial y}{\partial \eta} \end{vmatrix} = \frac{\partial x}{\partial \xi} \frac{\partial y}{\partial \eta} - \frac{\partial y}{\partial \xi} \frac{\partial x}{\partial \eta} \quad (3.25)$$

The partial derivatives that appear in (3.25) can be calculated by substituting (3.20)-(3.23) into (3.17) and (3.18), and by performing the appropriate partial differentiation. After algebraic manipulations, (3.25) can be written as

$$|J| = \frac{1}{8}(a + b\xi + c\eta) \quad (3.26)$$

where

$$a = (x_1 - x_3)(y_2 - y_4) - (x_2 - x_4)(y_1 - y_3) \quad (3.27)$$

$$b = [-(x_1 - x_2)(y_3 - y_4) + (x_3 - x_4)(y_1 - y_2)] \quad (3.28)$$

$$c = [-(x_1 - x_4)(y_2 - y_3) + (x_2 - x_3)(y_1 - y_4)] \quad (3.29)$$

### 3.1.2. Computation of Integrals

Of all the terms included in the integrands that appear in (3.10), only  $\omega_i^e$ ,  $(T^e)^{t+1}$  and the dirac delta functions (namely,  $\delta(x - x_s, y - y_s)$ ,  $\delta(x - x_{lk}, y - y_{lk})$  and  $\delta(x - x_{td}, y - y_{td})$ ) are spatial functions. The rest of the terms of the integrands are either constant over an element or only functions of time (refer to the following sections which demonstrate that land subsidence, stream-groundwater interaction, lake-groundwater interaction and tile drain/subsurface irrigation flows over an element as functions of time

only). It should be noted that the boundary flow,  $\sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} \iint_{\Gamma^e} q_{\Gamma^e}^{t+1} \omega_i^e d\Gamma^e$ , is a part of the

boundary conditions and its value should already be available. A common practice in finite element method is to assume that the transmissivity,  $(T^e)^{t+1}$ , is constant over an individual element but differs from one element to another. In IWFM,  $(T^e)^{t+1}$  is

computed as the average transmissivity over an element. Approximating  $(T^e)^{t+1}$  using the element shape functions and averaging it over an element  $e$ , one obtains

$$(T^e)^{t+1} = \frac{1}{A^e} \iint_{\Omega^e} \left( \sum_{j=1}^{n_e} T_j^{t+1} \omega_j^e \right) d\Omega^e \quad (3.30)$$

where

$n_e$  = number of nodes that constitute element  $e$ ; 3 for a triangular element and 4 for a quadrilateral element, (dimensionless);

$A^e$  = area of element  $e$ , ( $L^2$ );

$T_j^{t+1}$  = transmissivity at the  $j^{\text{th}}$  node that constitute element  $e$ , ( $L^2/T$ ).

Once the elemental transmissivity,  $(T^e)^{t+1}$ , is defined, IWFM utilizes a simplification procedure on the conductance term (third integral of equation (3.10)) in order to decrease the required computer storage. At node  $i$ , the conductance term is expressed as

$$\begin{aligned} & \sum_{j=N \cdot (m-1)+1}^{N \cdot m} \iint_{\Omega^e} (T^e)^{t+1} h_j^{t+1} \left( \frac{\partial \omega_i^e}{\partial x} \frac{\partial \omega_j^e}{\partial x} + \frac{\partial \omega_i^e}{\partial y} \frac{\partial \omega_j^e}{\partial y} \right) d\Omega^e \\ &= (T^e)^{t+1} \iint_{\Omega^e} \left( \sum_{\substack{j=N \cdot (m-1)+1 \\ j \neq i}}^{N \cdot m} \left( \bar{\nabla} \omega_i^e \bar{\nabla} \omega_j^e h_j^{t+1} \right) + \bar{\nabla} \omega_i^e \bar{\nabla} \omega_i^e h_i^{t+1} \right) d\Omega^e \quad (3.31) \end{aligned}$$

In equation (3.31), the  $i^{\text{th}}$  term of the summation is simply separated from the summation notation. It can be shown that the shape functions for both linear triangular and bilinear quadrilateral elements sum up to unity:

$$\sum_{j=N \cdot (m-1)+1}^{N \cdot m} \omega_j^e = 1 \quad (3.32)$$

From (3.32)

$$\sum_{j=N \cdot (m-1)+1}^{N \cdot m} \bar{\nabla} \omega_j^e = \bar{\nabla} \omega_i^e + \sum_{\substack{j=N \cdot (m-1)+1 \\ j \neq i}}^{N \cdot m} \bar{\nabla} \omega_j^e = 0 \quad (3.33)$$

or

$$\bar{\nabla} \omega_i^e = - \sum_{\substack{j=N \cdot (m-1)+1 \\ j \neq i}}^{N \cdot m} \bar{\nabla} \omega_j^e \quad (3.34)$$

Substituting (3.34) into (3.31) results in

$$\begin{aligned} & \sum_{j=N \cdot (m-1)+1}^{N \cdot m} \iint_{\Omega^e} (T^e)^{t+1} h_j^{t+1} \left( \frac{\partial \omega_i^e}{\partial x} \frac{\partial \omega_j^e}{\partial x} + \frac{\partial \omega_i^e}{\partial y} \frac{\partial \omega_j^e}{\partial y} \right) d\Omega^e \\ &= (T^e)^{t+1} \iint_{\Omega^e} \left( \sum_{\substack{j=N \cdot (m-1)+1 \\ j \neq i}}^{N \cdot m} (\bar{\nabla} \omega_i^e \bar{\nabla} \omega_j^e h_j^{t+1}) - \sum_{\substack{j=N \cdot (m-1)+1 \\ j \neq i}}^{N \cdot m} (\bar{\nabla} \omega_i^e \bar{\nabla} \omega_j^e h_i^{t+1}) \right) d\Omega^e \\ &= -(T^e)^{t+1} \iint_{\Omega^e} \left( \sum_{\substack{j=N \cdot (m-1)+1 \\ j \neq i}}^{N \cdot m} \bar{\nabla} \omega_i^e \bar{\nabla} \omega_j^e (h_i^{t+1} - h_j^{t+1}) \right) d\Omega^e \end{aligned} \quad (3.35)$$

After substituting (3.30) and (3.35) into (3.10), the only spatial functions defined over an element are the element shape functions. The rest of the terms included in the integrands can be moved out of the integrals. After this procedure only the following integrals remain to be computed for each element in (3.10):

$$\iint_{\Omega^e} \omega_i^e d\Omega^e \quad (3.36)$$

$$\iint_{\Omega^e} \delta(x - x_o, y - y_o) \omega_i^e d\Omega^e \quad (3.37)$$

$$\iint_{\Omega^e} \left( \frac{\partial \omega_i^e}{\partial x} \frac{\partial \omega_j^e}{\partial x} + \frac{\partial \omega_i^e}{\partial y} \frac{\partial \omega_j^e}{\partial y} \right) d\Omega^e \quad (3.38)$$

In (3.37)  $x_o$  and  $y_o$  represent either the coordinates of a stream location,  $(x_s, y_s)$ , the coordinates of a lake location,  $(x_{lk}, y_{lk})$ , or the coordinates of a tile drain/subsurface irrigation system,  $(x_{td}, y_{td})$ , depending on the integral being computed in (3.10).

### 3.1.2.a. Integration over Triangular Elements

After substituting any of the equations (3.13)-(3.15) into (3.36), it can be shown that (Huyakorn and Pinder, 1983)

$$\iint_{\Omega^e} \omega_i^e d\Omega^e = \frac{A^e}{3} \quad (3.39)$$

where  $A^e$  is the area of the triangular element and it is given in equation (3.16).

In IWFEM, it is assumed that the integral in (3.37) yields the area of stream, lake or tile drain/subsurface irrigation system that lies over the part element  $e$  that is associated with node  $i$ :

$$\iint_{\Omega^e} \delta(x - x_o, y - y_o) \omega_i^e d\Omega^e \cong A_{o,i}^e \quad (3.40)$$

where  $A_{o,i}^e$  is the elemental area of the stream, lake or tile drain/subsurface irrigation system depending on the integral being computed in (3.10).

By differentiating the equations (3.13)-(3.15) with respect to  $x$  and  $y$ , and substituting them into (3.38) one obtains (Huyakorn and Pinder, 1983)

$$\begin{aligned} & \iint_{\Omega^e} \left( \frac{\partial \omega_i^e}{\partial x} \frac{\partial \omega_j^e}{\partial x} + \frac{\partial \omega_i^e}{\partial y} \frac{\partial \omega_j^e}{\partial y} \right) d\Omega^e \\ &= \frac{1}{4A^e} \left[ (y_j - y_k)(y_k - y_i) + (x_j - x_k)(x_k - x_i) \right] \end{aligned} \quad (3.41)$$

### 3.1.2.b. *Integration over Quadrilateral Elements*

IWFM utilizes the coordinate transformation from  $(x, y)$  space into  $(\xi, \eta)$  space and uses 2-point Gaussian quadrature technique in order to calculate the integrals in (3.36) and (3.38) numerically for quadrilateral elements (Gerald and Wheatley, 1994). Using the equality given in (3.24)

$$\iint_{\Omega^e} \omega_i^e(x, y) d\Omega^e = \int_{-1}^1 \int_{-1}^1 \omega_i^e(\xi, \eta) |J| d\xi d\eta \quad (3.42)$$

where  $\omega_i(\xi, \eta)$  is given in (3.19).

Application of the 2-point Gaussian quadrature on the integral in (3.42) results in

$$\begin{aligned}
& \int_{-1}^1 \int_{-1}^1 \omega_i^e(\xi, \eta) |J| d\xi d\eta \\
&= \int_{-1}^1 \int_{-1}^1 G(\xi, \eta) d\xi d\eta \\
&\cong \left[ G\left(\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}\right) + G\left(\frac{1}{\sqrt{3}}, -\frac{1}{\sqrt{3}}\right) + G\left(-\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}\right) + G\left(-\frac{1}{\sqrt{3}}, -\frac{1}{\sqrt{3}}\right) \right] \quad (3.43)
\end{aligned}$$

where  $G(\xi, \eta) = \omega_i^e(\xi, \eta) |J|$  and  $|J|$  is given in (3.26).

Similar to the assumption made for triangular elements, it is assumed that the integral given in (3.37) is equal to the area of stream, lake or tile drain/subsurface irrigation system over the part of quadrilateral element  $e$  that is associated with node  $i$ :

$$\iint_{\Omega^e} \delta(x - x_o, y - y_o) \omega_i^e d\Omega^e \cong A_{o,i}^e \quad (3.44)$$

To compute the integral in (3.38) for a quadrilateral element, it is necessary to define the partial derivatives in terms of  $\xi$  and  $\eta$ . Using the chain rule, one obtains

$$\frac{\partial \omega_i^e}{\partial \xi} = \frac{\partial \omega_i^e}{\partial x} \frac{\partial x}{\partial \xi} + \frac{\partial \omega_i^e}{\partial y} \frac{\partial y}{\partial \xi}$$

$$\frac{\partial \omega_i^e}{\partial \eta} = \frac{\partial \omega_i^e}{\partial x} \frac{\partial x}{\partial \eta} + \frac{\partial \omega_i^e}{\partial y} \frac{\partial y}{\partial \eta}$$

which can be expressed in matrix form as

$$\begin{Bmatrix} \frac{\partial \omega_i^e}{\partial \xi} \\ \frac{\partial \omega_i^e}{\partial \eta} \end{Bmatrix} = \mathbf{J} \begin{Bmatrix} \frac{\partial \omega_i^e}{\partial x} \\ \frac{\partial \omega_i^e}{\partial y} \end{Bmatrix} \quad (3.45)$$

where  $J = \begin{bmatrix} \frac{\partial x}{\partial \xi} & \frac{\partial y}{\partial \xi} \\ \frac{\partial x}{\partial \eta} & \frac{\partial y}{\partial \eta} \end{bmatrix}$  is the Jacobian of the transformation whose determinant is given in

(3.25). Equation (3.45) can be solved for  $\frac{\partial \omega_i^e}{\partial x}$  and  $\frac{\partial \omega_i^e}{\partial y}$  using matrix algebra:

$$\begin{Bmatrix} \frac{\partial \omega_i^e}{\partial x} \\ \frac{\partial \omega_i^e}{\partial y} \end{Bmatrix} = J^{-1} \begin{Bmatrix} \frac{\partial \omega_i^e}{\partial \xi} \\ \frac{\partial \omega_i^e}{\partial \eta} \end{Bmatrix} \quad (3.46)$$

In (3.46),  $|J|$  stands for the determinant of the Jacobian, which is given in (3.25).

Based on these results, the integral in (3.38) can be transformed into the  $(\xi, \eta)$  space as

$$\begin{aligned} & \iint_{\Omega^e} \left( \frac{\partial \omega_i^e}{\partial x} \frac{\partial \omega_j^e}{\partial x} + \frac{\partial \omega_i^e}{\partial y} \frac{\partial \omega_j^e}{\partial y} \right) d\Omega^e \\ &= \int_{-1}^1 \int_{-1}^1 G(\xi, \eta) d\xi d\eta \\ &\cong \left[ G\left(\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}\right) + G\left(\frac{1}{\sqrt{3}}, -\frac{1}{\sqrt{3}}\right) + G\left(-\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}\right) + G\left(-\frac{1}{\sqrt{3}}, -\frac{1}{\sqrt{3}}\right) \right] \end{aligned} \quad (3.47)$$

where

$$G(\xi, \eta) = \frac{1}{|J|} \left\{ \left( \frac{\partial y}{\partial \eta} \frac{\partial \omega_i^e}{\partial \xi} - \frac{\partial y}{\partial \xi} \frac{\partial \omega_i^e}{\partial \eta} \right) \left( \frac{\partial y}{\partial \eta} \frac{\partial \omega_j^e}{\partial \xi} - \frac{\partial y}{\partial \xi} \frac{\partial \omega_j^e}{\partial \eta} \right) \right. \\ \left. + \left( -\frac{\partial x}{\partial \eta} \frac{\partial \omega_i^e}{\partial \xi} + \frac{\partial x}{\partial \xi} \frac{\partial \omega_i^e}{\partial \eta} \right) \left( -\frac{\partial x}{\partial \eta} \frac{\partial \omega_j^e}{\partial \xi} + \frac{\partial x}{\partial \xi} \frac{\partial \omega_j^e}{\partial \eta} \right) \right\} \quad (3.48)$$

The integral  $\iint_{\Omega^e} \omega_i^e d\Omega^e$  in (3.36) can be interpreted as the part of the area of element  $e$  that is associated with node  $i$ . Summation of all such areas of elements that connect at node  $i$  defines the total area that is associated with node  $i$  (Figure 3.4). Therefore, one can express the area associated with a node  $i$  as

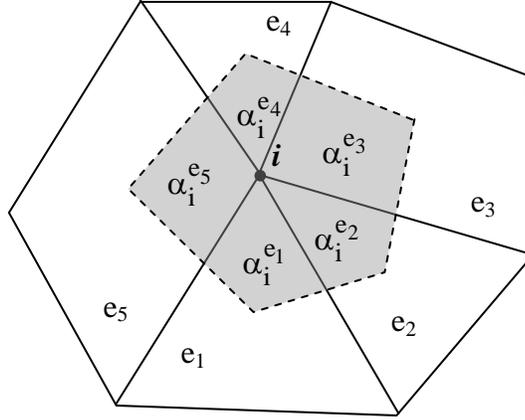

$$A_i = \sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} A_i^e \quad (3.49)$$

where

$$A_i^e = \iint_{\Omega^e} \omega_i^e d\Omega^e = \text{part of the area of element } e \text{ that is associated with node } i, (L^2);$$

$$A_i = \text{total area associated with a node } i, (L^2).$$

To be able to solve equation (3.10) numerically, it is also necessary to discretize the vertical flows, subsidence, stream-groundwater interaction, lake-groundwater interaction and tile drains/subsurface irrigation terms as well as boundary and initial conditions. In the following sections, the temporal and spatial discretization of these terms will be discussed.

**Figure 3.4** Total area that is associated with node  $i$

### 3.1.3. Vertical Flows when Aquifers are Separated by an Aquitard

The head difference between the aquifer layer in consideration (i.e. layer  $m$ ) and the upper adjacent layer (i.e. layer  $m-1$ ) is expressed in the finite element notation as

$$\left(\Delta h_i^u\right)^{t+1} = \begin{cases} h_i^{t+1} - h_{i-N}^{t+1} & \text{if } h_i^t \geq z_{b_i} \ ; \ h_{i-N}^t > z_{t_i} \\ z_{b_i} - h_{i-N}^{t+1} & \text{if } h_i^t < z_{b_i} \ ; \ h_{i-N}^t > z_{t_i} \\ h_i^{t+1} - z_{t_i} & \text{if } h_i^t \geq z_{b_i} \ ; \ h_{i-N}^t = z_{t_i} \\ 0 & \text{if } h_i^t < z_{b_i} \ ; \ h_{i-N}^t = z_{t_i} \end{cases} \quad (3.50)$$

where

- $h_i$  = head at node  $i$ , (L);
- $h_{i-N}$  = head at upper adjacent node, (L);
- $z_{b_i}$  = bottom elevation of the aquitard at node  $i$ , (L);
- $z_{t_i}$  = top elevation of the aquitard at node  $i$ , (L);
- $t$  = index for previous time step, (dimensionless);

$t+1$  = index for present time step, (dimensionless).

It should be noted that the decision on how to compute  $(\Delta h_i^u)^{t+1}$  in (3.50) is based on the known head values at time step  $t$ . During the development of IWFM, it has been observed that using the unknown head values at time step  $t+1$  to perform the above computations creates convergence problems. On the other hand, the formulation given in equation (3.50) results in robust solutions.

Similarly, the head difference between the aquifer in consideration (i.e. layer  $m$ ) and the lower adjacent layer (i.e. layer  $m+1$ ) can be expressed in the finite element notation as

$$(\Delta h_i^d)^{t+1} = \begin{cases} h_i^{t+1} - h_{i+N}^{t+1} & \text{if } h_i^t \geq z_{t_i} ; h_{i+N}^t \geq z_{b_i} \\ z_{t_i} - h_{i+N}^{t+1} & \text{if } h_i^t = z_{t_i} ; h_{i+N}^t \geq z_{b_i} \\ h_i^{t+1} - z_{t_i} & \text{if } h_i^t \geq z_{t_i} ; h_{i+N}^t < z_{b_i} \\ 0 & \text{if } h_i^t = z_{t_i} ; h_{i+N}^t < z_{b_i} \end{cases} \quad (3.51)$$

Substituting (3.50) and (3.51) into equation (3.10), one can express the vertical flow terms as

$$\begin{aligned} & \sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} H(m-2) \iint_{\Omega^e} L_{i-N} (\Delta h_i^u)^{t+1} \omega_i^e d\Omega^e \\ & = H(m-2) L_{i-N} (\Delta h_i^u)^{t+1} A_i \end{aligned} \quad (3.52)$$

$$\begin{aligned}
& \sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} [1-H(m-N_L)] \iint_{\Omega^e} L_{i+N} (\Delta h_i^d)^{t+1} \omega_1^e d\Omega^e \\
& = [1-H(m-N_L)] L_{i+N} (\Delta h_i^d)^{t+1} A_i
\end{aligned} \tag{3.53}$$

### 3.1.4. Vertical Flows when Aquifers are not Separated by an Aquitard

As in the previous section, the head difference between the aquifer layer in consideration and the upper adjacent layer can be expressed in finite element notation as

$$\left( \Delta h_i^u \right)^{t+1} = \begin{cases} h_i^{t+1} - h_{i-N}^{t+1} & \text{if } h_i^t \geq z_{k_i} \ ; \ h_{i-N}^t > z_{k_i} \\ z_{k_i} - h_{i-N}^{t+1} & \text{if } h_i^t < z_{k_i} \ ; \ h_{i-N}^t > z_{k_i} \\ h_i^{t+1} - z_{k_i} & \text{if } h_i^t \geq z_{k_i} \ ; \ h_{i-N}^t = z_{k_i} \\ 0 & \text{if } h_i^t < z_{k_i} \ ; \ h_{i-N}^t = z_{k_i} \end{cases} \tag{3.54}$$

where

$z_{k_i}$  = elevation of the interface between the aquifer in consideration and the upper adjacent aquifer layer at node  $i$ , (L).

Similarly, one can express the discretized head difference between the aquifer and the lower adjacent aquifer layer as

$$\left( \Delta h_i^d \right)^{t+1} = \begin{cases} h_i^{t+1} - h_{i+N}^{t+1} & \text{if } h_i^t \geq z_{k_i} \ ; \ h_{i+N}^t \geq z_{k_i} \\ z_{k_i} - h_{i+N}^{t+1} & \text{if } h_i^t = z_{k_i} \ ; \ h_{i+N}^t \geq z_{k_i} \\ h_i^{t+1} - z_{k_i} & \text{if } h_i^t \geq z_{k_i} \ ; \ h_{i+N}^t < z_{k_i} \\ 0 & \text{if } h_i^t = z_{k_i} \ ; \ h_{i+N}^t < z_{k_i} \end{cases} \tag{3.55}$$

### 3.1.5. Land Subsidence

The expression for the rate of flow out of storage due to land subsidence,  $q_{sd}$ , is already given in previous chapter. Utilizing this expression and the approximate head field from equation (3.2),  $q_{sd}$  at an aquifer layer  $m$  can approximately be expressed as

$$q_{sd} \cong \sum_{j=N \cdot (m-1)+1}^{N \cdot m} S'_{sj} \frac{\partial h_j}{\partial t} \omega_j \quad m = 1, \dots, N_L \quad (3.56)$$

Equation (3.56) is the spatially discretized version of the rate of flow out of storage due to land subsidence. To discretize (3.56) in time, IWFM uses the methodology described by Leake and Prudic (1988):

$$q_{sd}^{t+1} = \sum_{j=N \cdot (m-1)+1}^{N \cdot m} \left\{ (S'_{sj})^t \frac{(h_j^{t+1} - h_{c_j}^t)}{\Delta t} + S_{sej} b_{oj}^t \frac{(h_{c_j}^t - h_j^t)}{\Delta t} \right\} \omega_j \quad (3.57)$$

where

$$(S'_{sj})^t = \begin{cases} S_{sej} b_{oj}^t & \text{if } h_j^{t+1} > h_{c_j}^t \\ S_{sij} b_{oj}^t & \text{if } h_j^{t+1} \leq h_{c_j}^t \end{cases} \quad (3.58)$$

$S_{sej}$  = elastic specific storage at node  $j$ , (1/L);

$S_{sij}$  = inelastic specific storage at node  $j$ , (1/L);

$b_{oj}$  = the thickness of the interbed at node  $j$ , (L);

$h_{c_j}$  = pre-consolidation head at node  $j$ , (L).

Multiplying (3.57) by element shape functions,  $\omega_i^e$ , integrating over individual elements and utilizing the mass lumping technique previously, one obtains

$$\sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} \iint_{\Omega^e} q_{sd}^{t+1} \omega_i^e d\Omega^e \cong \left\{ (S'_{si})^t \frac{(h_i^{t+1} - h_{ci}^t)}{\Delta t} + S_{se1} b_{oi}^t \frac{(h_{ci}^t - h_i^t)}{\Delta t} \right\} A_i \quad (3.59)$$

Once the groundwater flow equation is solved for a time step, the total compaction at a node can be computed by inserting the change in head,  $\Delta h_i^{t+1} = h_i^{t+1} - h_i^t$ , into expressions for the elastic and inelastic change in the interbed thickness given in previous chapter, and summing the elastic and inelastic compactations:

$$\Delta b_{oi}^{t+1} = \Delta b_{se1}^{t+1} + \Delta b_{si1}^{t+1} \quad (3.60)$$

$$\Delta b_{se1}^{t+1} = -\Delta h_i^{t+1} S_{se1} b_{oi}^t \quad (3.61)$$

$$\Delta b_{si1}^{t+1} = -\Delta h_i^{t+1} S_{si1} b_{oi}^t \quad (3.62)$$

Finally, the thickness of the interbed at a node can be computed by

$$b_{oi}^{t+1} = b_{oi}^t - \Delta b_{oi}^{t+1} \quad (3.63)$$

In (3.63), the change in the interbed thickness,  $\Delta b_{oi}^{t+1}$ , is subtracted from the previous thickness of the interbed,  $b_{oi}^t$ , since a positive value represents compaction.

If an inelastic compaction occurs, it is also necessary to modify the pre-compaction head. In this case, the pre-compaction head is assigned the new head at the groundwater node:

$$h_{c_i}^{t+1} = \begin{cases} h_{c_i}^t & \text{if } h_i^{t+1} \geq h_{c_i}^t \\ h_i^{t+1} & \text{if } h_i^{t+1} < h_{c_i}^t \end{cases} \quad (3.64)$$

### 3.1.6. Stream-Groundwater Interaction

The expression for stream-groundwater interaction,  $Q_{\text{sint}}$ , that occurs at a section of the stream represented by a stream node is given in previous chapter. In IWFEM, it is required that a stream node coincides with a groundwater node. Utilizing the expression for  $Q_{\text{sint}}$  as given in previous chapter, one can write

$$\begin{aligned} & \delta(x - x_s, y - y_s) \frac{Q_{\text{sint}}^{t+1}}{A_s} \\ & \cong \sum_{j=N(m-1)+1}^{N \cdot m} \delta(x - x_s, y - y_s) \frac{C_{s_j} \left[ \max(h_{s_j}^{t+1}, h_{b_j}) - \max(h_j^{t+1}, h_{b_j}) \right]}{A_{s_j}} \omega_j \end{aligned} \quad (3.65)$$

where

- $C_{s_j}$  = stream bed conductance at groundwater node  $j$ , ( $L^2/T$ );
- $h_{s_j}$  = stream surface elevation at groundwater node  $j$ , ( $L$ );
- $h_{b_j}$  = elevation of the stream bottom at groundwater node  $j$ , ( $L$ );
- $A_{s_j}$  = effective area of the stream segment at groundwater node  $j$ , ( $L^2$ ).

Equation (3.65) is valid only at the groundwater nodes where a stream node exists. Mathematically, this is represented by multiplying by the dirac delta function,  $\delta(x - x_s, y - y_s)$ , as shown in equation (3.65). Furthermore, (3.65) is defined for all

aquifer layers only for the completeness of the mathematical derivation. In reality, stream nodes coincide with only the groundwater nodes at the top most layer (i.e.  $m=1$ ) and (3.65) vanishes for other aquifer layers (i.e.  $m = 2, \dots, N_L$ ).

After multiplying (3.65) by the element shape functions,  $\omega_i^e$  and integrating over individual elements, one obtains

$$\begin{aligned}
& \sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} \iint_{\Omega^e} \delta(x - x_s, y - y_s) \frac{Q_{\text{shint}}^{t+1}}{A_s} \omega_i^e d\Omega^e \\
&= \frac{C_{s_i} \left[ \max(h_{s_i}^{t+1}, h_{b_i}) - \max(h_i^{t+1}, h_{b_i}) \right]}{A_{s_i}} \sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} \iint_{\Omega^e} \delta(x - x_s, y - y_s) \omega_i^e d\Omega^e \\
&= C_{s_i} \left[ \max(h_{s_i}^{t+1}, h_{b_i}) - \max(h_i^{t+1}, h_{b_i}) \right] \tag{3.66}
\end{aligned}$$

Due to the expressions given in (3.40) and (3.44), the following equivalence is used in (3.66):

$$A_{s_i} = \sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} \iint_{\Omega^e} \delta(x - x_s, y - y_s) \omega_i^e d\Omega^e \tag{3.67}$$

### 3.1.7. Lake-Groundwater Interaction

The expression for lake-groundwater interaction,  $Q_{\text{lkint}}$ , that occurs through an effective area of the lake represented by a lake node is given in previous chapter. In IWFEM, it is required that a lake node coincides with a groundwater node. Utilizing the expression for  $Q_{\text{lkint}}$  as given in previous chapter, one can write

$$\begin{aligned}
& \delta(x - x_{lk}, y - y_{lk}) \frac{Q_{lkint}^{t+1}}{A_{lk}} \\
& \equiv \sum_{j=N_e(m-1)+1}^{N_e m} \delta(x - x_{lk}, y - y_{lk}) \frac{C_{lkj} \left[ \max(h_{lk}^{t+1}, h_{blkj}) - \max(h_j^{t+1}, h_{blkj}) \right]}{A_{lkj}} \omega_j \quad (3.68)
\end{aligned}$$

where

$$\begin{aligned}
C_{lkj} &= \text{lake bed conductance at groundwater node } j, (L^2/T); \\
h_{lk} &= \text{lake surface elevation, (L)}; \\
h_{blkj} &= \text{elevation of the lake bottom at groundwater node } j, (L); \\
A_{lkj} &= \text{effective area of the lake at groundwater node } j, (L^2).
\end{aligned}$$

After multiplying (3.68) by the element shape functions,  $\omega_i^e$  and integrating over individual elements, one obtains

$$\begin{aligned}
& \sum_{e=N_e(m-1)+1}^{N_e m} \iint_{\Omega^e} \delta(x - x_{lk}, y - y_{lk}) \frac{Q_{lkint}^{t+1}}{A_{lk}} \omega_i^e d\Omega^e \\
& = \frac{C_{lk_i} \left[ \max(h_{lk}^{t+1}, h_{blk_i}) - \max(h_i^{t+1}, h_{blk_i}) \right]}{A_{lk_i}} \sum_{e=N_e(m-1)+1}^{N_e m} \iint_{\Omega^e} \delta(x - x_{lk}, y - y_{lk}) \omega_i^e d\Omega^e \\
& = C_{lk_i} \left[ \max(h_{lk}^{t+1}, h_{blk_i}) - \max(h_i^{t+1}, h_{blk_i}) \right] \quad (3.69)
\end{aligned}$$

Due to the expressions given in (3.40) and (3.44), the following equivalence is used in (3.69):

$$A_{lk_i} = \sum_{e=N_e(m-1)+1}^{N_e m} \iint_{\Omega^e} \delta(x - x_{lk}, y - y_{lk}) \omega_i^e d\Omega^e \quad (3.70)$$

In equations (3.68)-(3.69), the lake surface elevation,  $h_{lk}^{t+1}$ , appears without the subscript for the corresponding groundwater node. This is due to the fact that the changes in the lake surface elevation over an individual lake are assumed to be negligible in IWFEM. For this reason, the same lake surface elevation prevails for all lake nodes that represent an individual lake.

### 3.1.8. Tile Drains and Subsurface Irrigation

Similar to stream-groundwater interaction and lake-groundwater interaction, the term for the tile drains/subsurface irrigation can also be discretized as follows:

$$\begin{aligned} & \delta(x - x_{td}, y - y_{td}) \frac{Q_{td}^{t+1}}{A_{td}} \\ & \cong \sum_{j=N \cdot (m-1) + 1}^{N \cdot m} \delta(x - x_{td}, y - y_{td}) \frac{C_{tdj} (z_{tdj} - h_j^{t+1})}{A_{tdj}} \omega_j \end{aligned} \quad (3.71)$$

where

- $C_{tdj}$  = conductance of the interface material between the tile drain/subsurface irrigation system at groundwater node  $j$ , ( $L^2/T$ );
- $z_{tdj}$  = elevation of the tile drain or the head at the subsurface irrigation system, (L);
- $A_{tdj}$  = effective area through which tile drain outflow or subsurface irrigation inflow at groundwater node  $j$  is occurring, ( $L^2$ ).

After multiplying (3.71) by the element shape functions,  $\omega_i^e$  and integrating over individual elements, one obtains

$$\begin{aligned}
& \sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} \iint_{\Omega^e} \delta(x - x_{td}, y - y_{td}) \frac{Q_{td}^{t+1}}{A_{td}} \omega_i^e d\Omega^e \\
&= \frac{C_{td_i} (z_{td_i} - h_i^{t+1})}{A_{td_i}} \sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} \iint_{\Omega^e} \delta(x - x_{td}, y - y_{td}) \omega_i^e d\Omega^e \quad (3.72) \\
&= C_{td_i} (z_{td_i} - h_i^{t+1})
\end{aligned}$$

and

$$A_{td_i} = \sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} \iint_{\Omega^e} \delta(x - x_{td}, y - y_{td}) \omega_i^e d\Omega^e \quad (3.73)$$

### 3.1.9. Initial Conditions

The solution of equation (3.10) requires the knowledge of groundwater head values at the previous time step,  $t$ . Therefore, for the first time step, the head values at  $t = 0$  need to be defined by the user ( i.e. initial head values  $h_i^{t=0}$ ).

### 3.1.10. Boundary Conditions

Boundary conditions are also required to solve (3.10). Boundary conditions, as well as initial conditions, constrain the problem and make solutions unique. Boundary conditions are not only necessary in solving the groundwater equation, but the accuracy is important as well. If inconsistent or incomplete boundary conditions are specified, the problem is ill defined (Wang and Anderson, 1982).

IWFM has the functionality to incorporate the following boundary conditions into the groundwater equation: (i) specified flux (Neumann), (ii) specified head (Dirichlet), and (iii) general head. These boundary conditions can be constant over time or time-variant. In the following sections, the implementation of these boundary conditions into the numerical solution procedure will be discussed.

### ***3.1.10.a. Specified Flux (Neumann)***

In a finite element representation the specified flux value is multiplied by element shape functions and integrated over the element face for which the flux is specified:

$$\iint_{\Gamma^e} q_{\Gamma^e}^{t+1} \omega_i^e d\Gamma^e = - \iint_{\Gamma^e} f [x, y, (t+1) \cdot \Delta t] \omega_i^e d\Gamma^e \quad (3.74)$$

In IWFM,  $-\iint_{\Gamma^e} f [x, y, (t+1) \cdot \Delta t] \omega_i^e d\Gamma^e$  is the boundary flow specified by the user and evaluated at time  $(t+1) \cdot \Delta t$ . Equation (3.74) replaces the second integral term of equation (3.10).

### ***3.1.10.b. Specified Head (Dirichlet)***

In the case that the head is specified at a finite element node  $r$ , the  $r^{\text{th}}$  equation in the system of equations given in (3.10) becomes redundant. There is no longer a necessity to solve this equation since the head  $h_r^{t+1}$  at node  $r$  is known. Therefore, this equation is dropped from the system of equations.

### 3.1.10.c. General Head

The general head boundary inflow at a finite element node  $r$  can be expressed as

$$Q_{\text{GHB}_r}^{t+1} = \frac{K_r A_r}{d_r} (h_{\text{GHB}}^{t+1} - h_r^{t+1}) \quad (3.75)$$

where

- $Q_{\text{GHB}_r}$  = general head boundary flow at node  $r$ , ( $L^3/T$ );
- $K_r$  = hydraulic conductivity of the aquifer at node  $r$ , ( $L/T$ );
- $A_r$  = cross-sectional area at node  $r$  that flow passes through, ( $L^2$ );
- $d_r$  = distance between the boundary node  $r$  and the location of the known head, ( $L$ );
- $h_r$  = head value at the boundary node  $r$ , ( $L$ );
- $h_{\text{GHB}}$  = head at the nearby surface water body or aquifer, ( $L$ );
- $t$  = index for time step, (dimensionless).

When general head type boundary condition is defined at node  $r$ , equation (3.75) is subtracted from the  $r^{\text{th}}$  equation of the equation system (3.10).

## 3.2. Stream Flows

Equations given in previous chapter regarding the stream flows are already in algebraic form. Therefore, they are ready to be coupled with the discretized groundwater equation described in the preceding sections. The main stream flow equation can be re-written for the present time step as

$$Q_{s_i} (h_{s_i}^{t+1}) - Q_{\text{in}_i}^{t+1} + Q_{\text{bdiv}_i}^{t+1} + C_{s_i} \left[ \max(h_{s_i}^{t+1}, h_{b_i}) - \max(h_i^{t+1}, h_{b_i}) \right] = 0 \quad (3.76)$$

The explicit expression for the stream-groundwater interaction,  $Q_{\text{sint}_i}^{t+1}$ , has been substituted into (3.76). The expressions for  $Q_{\text{in}_i}^{t+1}$  and  $Q_{\text{bdiv}_i}^{t+1}$  are given in previous chapter. Equation (3.76) is coupled and solved simultaneously with equation (3.10) for stream surface elevation,  $h_{\text{s}_i}^{t+1}$ , and groundwater head at the stream node,  $h_i^{t+1}$ .

### 3.3. Lakes

The conservation equation for lake storage given in previous chapter is discretized as

$$\begin{aligned} & \frac{S_{\text{lk}}(h_{\text{lk}}^{t+1}) - S_{\text{lk}}(h_{\text{lk}}^t)}{\Delta t} - Q_{\text{brlk}}^{t+1} - Q_{\text{inlk}}^{t+1} + Q_{\text{lko}}^{t+1} \\ & - \sum_{i=1}^{N_{\text{lk}}} \left\{ P_{\text{lk}_i}^{t+1} A_{\text{lk}_i} - EV_{\text{lk}_i}^{t+1} A_{\text{lk}_i} \right. \\ & \left. - C_{\text{lk}_i} \left[ \max(h_{\text{lk}}^{t+1}, h_{\text{blk}_i}) - \max(h_i^{t+1}, h_{\text{blk}_i}) \right] \right\} = 0 \end{aligned} \quad (3.77)$$

In (3.77), the explicit expression for the lake-groundwater interaction,  $Q_{\text{lkint}_i}^{t+1}$ , has been used.

The total evaporation from the lake area represented by a lake node,  $EV_{\text{lk}_i}^{t+1} A_{\text{lk}_i}$ , is limited by the amount of water available at that lake node. This is represented in IWFM by the following formulation:

$$EV_{lk_i}^{t+1} A_{lk_i} \leq \frac{A_{lk_i}}{\Delta t} \max(h_{lk}^{t+1} - b_{lk_i}, 0) + P_{lk_i}^{t+1} A_{lk_i} + \frac{A_{lk_i}}{A_{lk}} (Q_{brlk}^{t+1} + Q_{inlk}^{t+1}) \quad (3.78)$$

Equation (3.78) suggests that the effect of precipitation and inflows to the water storage at a lake node is considered before the computation of evaporation. Also, the last term of equation (3.78) suggests that the inflows into the lake from diversions, bypasses and upstream lakes are distributed among the lake nodes evenly.

Equation (3.77) is valid when the lake surface elevation is less than the pre-specified maximum lake surface elevation,  $h_{lk_{max}}$ , or when the outflow from lake,  $Q_{lko}^{t+1}$ , is zero. If the lake surface elevation exceeds the maximum lake surface elevation, simply assigning  $h_{lk}^{t+1}$  to  $h_{lk_{max}}$  does not satisfy equation (3.77) and violates the requirement for the conservation of mass. In order to compute the lake outflow and still conserve mass by keeping lake elevation at its maximum, IWFM utilizes an alternative method.

Assuming that the groundwater head value is known, a function,  $F_{lk}$ , can be defined as equal to (3.77) less  $Q_{lko}^{t+1}$ :

$$F_{lk}(h_{lk}^{t+1}) = \frac{S_{lk}(h_{lk}^{t+1}) - S_{lk}(h_{lk}^t)}{\Delta t} - Q_{brlk}^{t+1} - Q_{inlk}^{t+1} - \sum_{i=1}^{N_{lk}} \left\{ P_{lk_i}^{t+1} A_{lk_i} - EV_{lk_i}^{t+1} A_{lk_i} - C_{lk_i} \left[ \max(h_{lk}^{t+1}, h_{blk_i}) - \max(h_i^{t+1}, h_{blk_i}) \right] \right\} \quad (3.79)$$

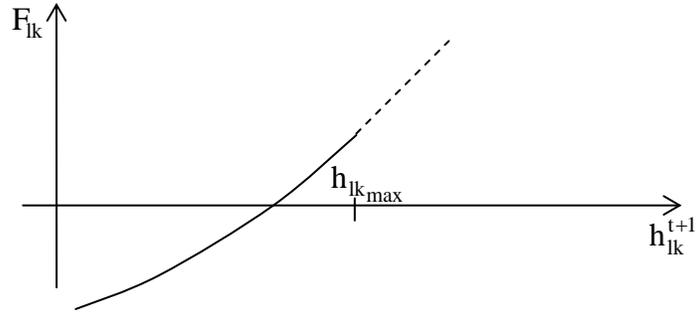

Equating (3.79) to zero and solving is equivalent to finding its root with respect to  $h_{lk}^{t+1}$ . Figures 3.5.a and 3.5.b show two possible cases when (3.79) is plotted as a function of  $h_{lk}^{t+1}$ . The dashed parts of the curves represent  $F_{lk}$  when  $h_{lk_{max}}$  is assumed to be large enough so that it does not have an effect on  $F_{lk}$ . However, in reality,  $F_{lk}$  is not defined beyond  $h_{lk_{max}}$ . When the root of (3.79) is below  $h_{lk_{max}}$  (Figure 3.5.a), lake outflow,  $Q_{lko}^{t+1}$ , is zero and the computed root also satisfies (3.77). On the other hand, when the root of  $F_{lk}$  is above  $h_{lk_{max}}$  (Figure 3.5.b), then  $Q_{lko}^{t+1}$  is non-zero. IWFM uses an iterative solution technique (namely, Newton-Raphson method which is explained later in this chapter) to find the root of (3.79). This method requires that the gradient of the function whose root is being sought for is non-zero and finite. In the case depicted in Figure 3.5.b, however, the gradient of  $F_{lk}$  at  $h_{lk_{max}}$  is infinite. In this case, IWFM modifies the function  $F_{lk}$  in the vicinity of  $h_{lk_{max}}$  so that the gradient of the modified function will be non-zero and finite and its root is guaranteed to be equal to  $h_{lk_{max}}$  (see Figure 3.5.c):

$$F_{lk}^* = \begin{cases} F_{lk} & \text{if } h_{lk}^{t+1} \leq h_{lk_{max}} - \varepsilon \\ G_{lk} & \text{if } h_{lk}^{t+1} > h_{lk_{max}} - \varepsilon \end{cases} \quad (3.80)$$

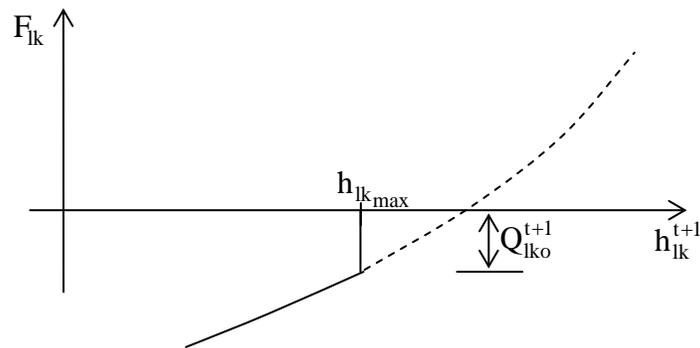

where

$$G_{lk} = F_{lk}(h_{lk_{max}}) \times \left[ 1 + \frac{h_{lk_{max}} - \varepsilon - h_{lk}^{t+1}}{\varepsilon} \right]; \quad (3.81)$$

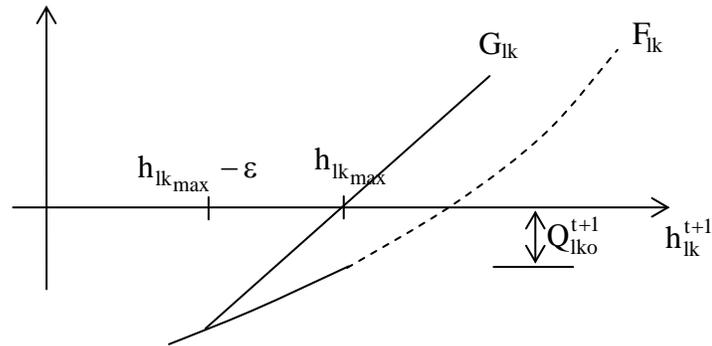

$$F_{lk}^* = \text{modified version of } F_{lk}.$$

(a) Lake elevation does not exceed the maximum lake surface elevation

(b) Lake elevation exceeds the maximum lake surface elevation

(c) Modified function,  $G_{lik}$ , when lake elevation exceeds the maximum elevation

**Figure 3.5** Plots of possible lake storage functions and the modified function when lake elevation exceeds the maximum elevation

$\varepsilon$  is chosen so that its value is small enough compared to the convergence criteria used for the iterative solution method. In this case, lake outflow,  $Q_{lko}^{t+1}$ , can be expressed as (Figure 3.5.c)

$$Q_{lko}^{t+1} = -F_{lk} \left( h_{lk_{max}} \right) \quad (3.82)$$

This approach allows for imposing the maximum lake elevation without disturbing the conservation of mass and the efficient use of numerical techniques for the solution of non-linear equations. Equation (3.77) is coupled and solved simultaneously with (3.10) for lake elevation,  $h_{lk}^{t+1}$ , and groundwater head at lake node,  $h_i^{t+1}$ .

### 3.4. Land Surface and Root Zone Flow Processes

Mathematical models used in IWFM for the simulation of land use and root zone flow processes are described in detail in another document (DWR, 2012) and they will not be covered in this documentation.

### 3.5. Soil Moisture in the Unsaturated Zone

The conservation equation that models the vertical movement of soil moisture in the unsaturated zone is discretized in IWFM as follows:

$$D_n^t \frac{\theta_{u,n}^{t+1} - \theta_{u,n}^t}{\Delta t} = Q_{in,n}^{t+1} - K_{u,n}^{t+1} \quad (3.83)$$

where

$D_n$  = thickness of layer n, (L);

- $\theta_{u,n}$  = soil moisture in the  $n^{\text{th}}$  unsaturated layer, (L/L);  
 $\Delta t$  = length of time step, (T);  
 $Q_{in,n}$  = inflow into unsaturated layer  $m$  from layer  $n-1$ , (L/T);  
 $K_{u,n}$  = unsaturated hydraulic conductivity of layer  $n$ , (L/T);  
 $t$  = time step, (dimensionless);  
 $n$  = unsaturated layer number, (dimensionless).

The unsaturated hydraulic conductivity in equation (3.83),  $K_{u,n}^{t+1}$ , can be represented either by Mualem-van Genuchten approach or Campbell's method:

$$K_{u,n}^{t+1} = \begin{cases} K_{s,n} \left( \frac{\theta_{u,n}^{t+1}}{\eta_{T,n}} \right)^{1/2} \left\{ 1 - \left[ 1 - \left( \frac{\theta_{u,n}^{t+1}}{\eta_{T,n}} \right)^{1/m} \right]^m \right\}^2 & ; \text{ van Genuchten-Mualem} \\ K_{s,n} \left( \frac{\theta_{u,n}^{t+1}}{\eta_{T,n}} \right)^{3 + \frac{2}{\lambda_n}} & ; \text{ Campbell} \end{cases} \quad (3.84)$$

and

$$m = \frac{\lambda_n}{\lambda_n + 1} \quad (3.85)$$

where

- $\eta_{T,n}$  = total porosity of the unsaturated layer  $n$ , (L/L);  
 $\lambda_n$  = pore size distribution index of unsaturated layer  $n$ , (dimensionless).

Due to the non-linearity of equation (3.83), it is solved for  $\theta_{u,n}^{t+1}$ , iteratively.

IWFM uses a combination of bisection and Newton's methods to solve for the soil moisture in the unsaturated layer n (Gerald and Wheatley, 1994). The iterative solution methodology starts and continues with Newton iterations:

$$\left(\theta_{u,n}^{t+1}\right)^{k+1} = \left(\theta_{u,n}^{t+1}\right)^k - \frac{F\left[\left(\theta_{u,n}^{t+1}\right)^k\right]}{F'\left[\left(\theta_{u,n}^{t+1}\right)^k\right]} \quad (3.86)$$

where

$$F\left[\left(\theta_{u,n}^{t+1}\right)^k\right] = \begin{cases} \begin{aligned} & Q_{in,n}^{t+1} - D_n^t \left( \frac{\left(\theta_{u,n}^{t+1}\right)^k - \theta_{u,n}^t}{\Delta t} \right) \\ & - K_{s,n} \left( \frac{\theta_{u,n}^{t+1}}{\eta_{T,n}} \right)^{1/2} \left\{ 1 - \left[ 1 - \left( \frac{\theta_{u,n}^{t+1}}{\eta_{T,n}} \right)^{1/m} \right]^m \right\}^2 \end{aligned} & ; \text{vGM} \\ \\ \begin{aligned} & Q_{in,n}^{t+1} - D_n^t \left( \frac{\left(\theta_{u,n}^{t+1}\right)^k - \theta_{u,n}^t}{\Delta t} \right) \\ & - K_{s,n} \left( \frac{\theta_{u,n}^{t+1}}{\eta_{T,n}} \right)^{3 + \frac{2}{\lambda_n}} \end{aligned} & ; \text{Campbell} \end{cases} \quad (3.87)$$

$$F' \left[ \left( \theta_{u,n}^{t+1} \right)^k \right] = \begin{cases} \frac{D_n^t}{\Delta t} - \frac{K_{s,n} G_1^2}{2\eta_{T,n} \sqrt{\frac{\left( \theta_{u,n}^{t+1} \right)^k}{\eta_{T,n}}}} \\ + 2m K_{s,n} G_1 G_2^{m-1} (dG_2) \sqrt{\frac{\left( \theta_{u,n}^{t+1} \right)^k}{\eta_{T,n}}} & ; \text{vGM} \\ \\ \frac{D_n^t}{\Delta t} \\ - K_{s,n} \left( \frac{3 + \frac{2}{\lambda_n}}{\eta_{T,n}} \right) \left( \frac{\left( \theta_{u,n}^{t+1} \right)^k}{\eta_{T,n}} \right)^{3 + \frac{2 - \lambda_n}{\lambda_n}} & ; \text{Campbell} \end{cases} \quad (3.88)$$

$$G_1 = 1 - G_2^m \quad (3.89)$$

$$G_2 = 1 - \left( \frac{\left( \theta_{u,n}^{t+1} \right)^k}{\eta_{T,n}} \right)^{1/m} \quad (3.90)$$

$$dG_2 = - \frac{1}{m \eta_{T,n}} \left( \frac{\left( \theta_{u,n}^{t+1} \right)^k}{\eta_{T,n}} \right)^{\frac{1-m}{m}} \quad (3.91)$$

In equations (3.86) - (3.91), k is the iteration number and vGM represents the van Genuchten-Mualem approach.

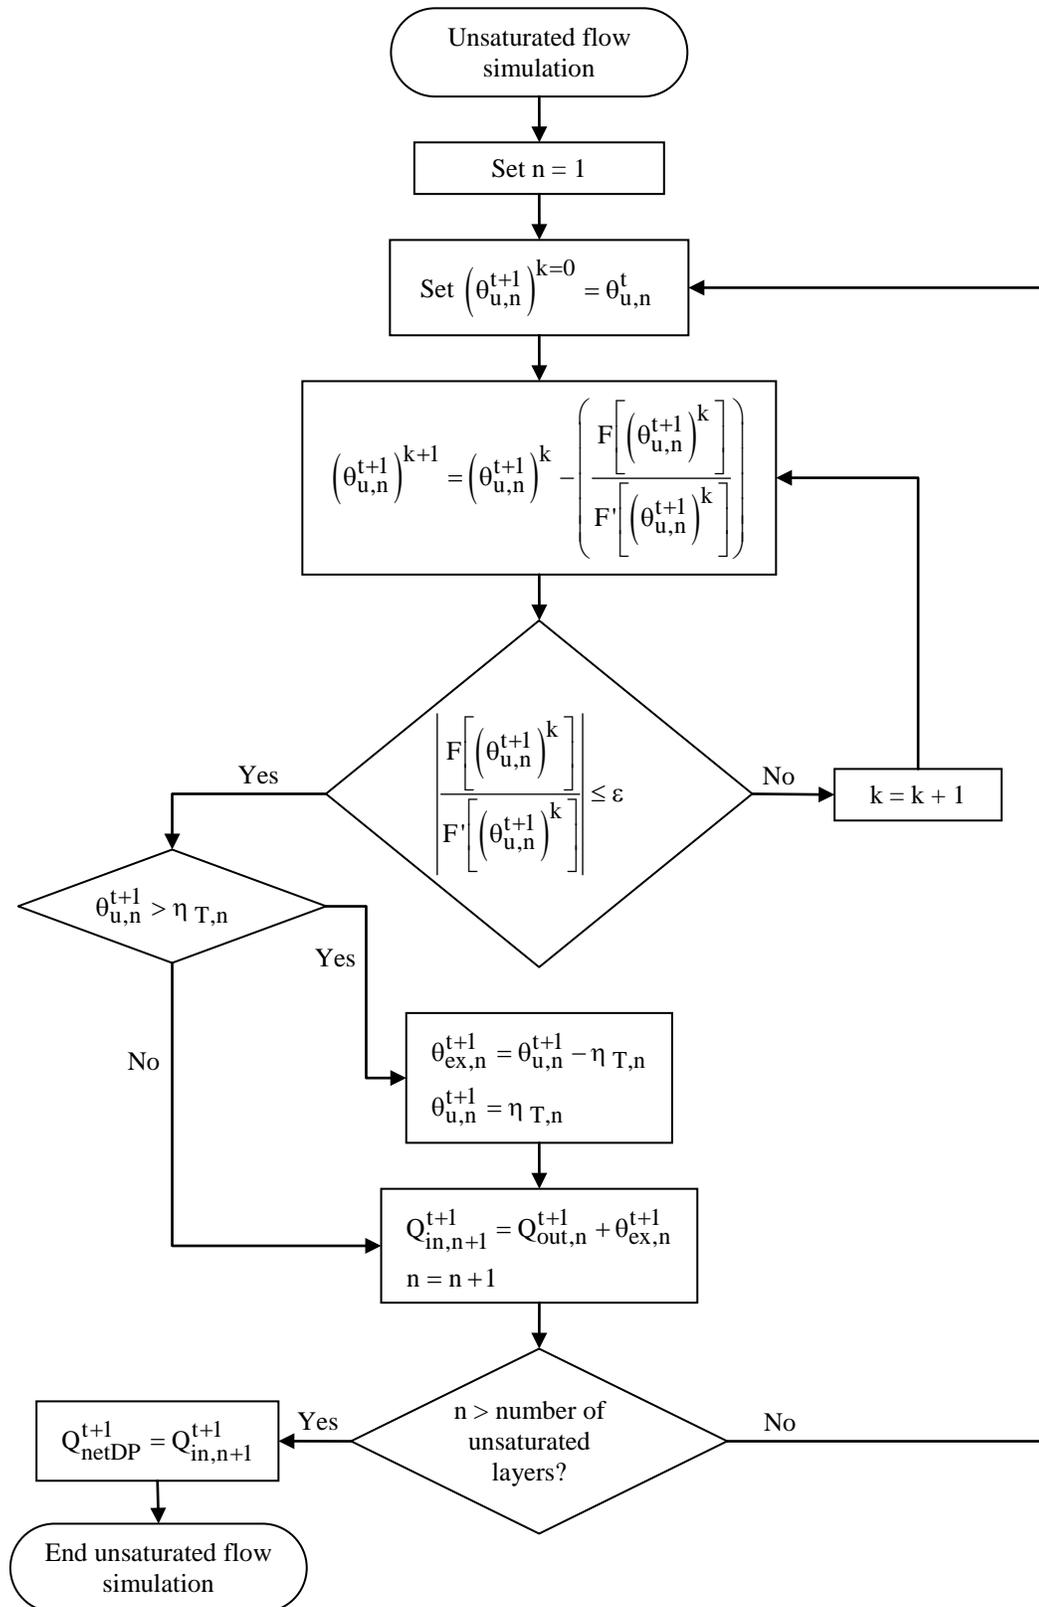

Newton's method is used until the estimate for the soil moisture goes above total porosity less 10% of the user-defined convergence tolerance for the iterative solver. At this point, bisection method is used as the iterative method. The reason for this switch

between the two methods is that the gradient of the van Genuchten-Mualem equation near saturation becomes very large and this causes problems for Newton's method. Bisection method has slower convergence but is more robust; therefore it is preferred when soil moisture is close to saturation.

Equation (3.86) is solved iteratively until a user-specified convergence level is achieved; i.e. until  $\left| \left( \theta_{u,m}^{t+1} \right)^{k+1} - \left( \theta_{u,m}^{t+1} \right)^k \right|$  is less than a pre-defined value.

The flowchart for the routing of moisture in a multi-layer unsaturated zone is illustrated in Figure 3.6. As shown in this figure, the water that percolates through the root zone is the inflow to the first unsaturated layer. First, the moisture content at the first unsaturated layer  $\left( \theta_{u,1}^{t+1} \right)$  is computed, iteratively. The outflow,  $Q_{out,1}^{t+1}$ , can then be redefined as a function of  $\left( \theta_{u,1}^{t+1} \right)^{k+1}$ . Based on the conservation of mass,  $Q_{out,2}^{t+1} = Q_{out,1}^{t+1}$ . Therefore, the soil moisture in layer 2 and the flow out of layer 2 are simulated in the same manner as layer 1. This procedure is performed for each layer until the net deep percolation into groundwater is calculated.

When simulating the soil moisture at each layer, IWFM checks that the soil moisture is less than or equal to the total porosity. If the soil moisture exceeds the total porosity of unsaturated layer n, the excess soil moisture,  $\theta_{ex,n}^{t+1}$  is assumed to drain due to gravitational force and is routed to unsaturated layer n+1, unless the layer is the last unsaturated layer within the system. The last layer's excess soil moisture is routed to the saturated groundwater below it.

**Figure 3.6** Flowchart for the unsaturated zone flow simulation

### 3.6. Small Watersheds

The conservation equation for the groundwater storage at a small watershed is discretized in IWFEM using the implicit discretization method:

$$S_{wg}^{t+1} = S_{wg}^t + (D_{wp}^{t+1} - Q_{wg}^{t+1} - Q_{wgs}^{t+1}) \Delta t \quad (3.92)$$

where

- $S_{wg}$  = groundwater storage within the small watershed boundary, ( $L^3$ );
- $D_{wp}$  = net deep percolation, i.e. recharge, to the groundwater storage within the small watershed domain, ( $L^3/T$ );
- $Q_{wg}$  = subsurface outflow from the small watershed that contributes to the groundwater storage at the modeled area, ( $L^3/T$ );
- $Q_{wgs}$  = contribution of groundwater storage to the surface flow at the small watershed, ( $L^3/T$ );
- $\Delta t$  = length of time step, (T);
- $t$  = index for time step, (dimensionless).

The net deep percolation,  $D_{wp}^{t+1}$ , is computed numerically using the same methodology described in the preceding section. Subsurface outflow from the small watershed,  $Q_{wg}^{t+1}$ , and the contribution of groundwater storage to the surface flow at the small watershed,  $Q_{wgs}^{t+1}$ , are computed as functions of the groundwater storage at the previous time step and the net deep percolation:

$$Q_{wg}^{t+1} = C_{wg} (S_{wg}^t + D_{wp}^{t+1}) \Delta t \quad (3.93)$$

$$Q_{wgs}^{t+1} = C_{ws} \left[ \left( S_{wg}^t + D_{wp}^{t+1} \right) \Delta t - S_{wgt} \right] \quad (3.94)$$

where

- $C_{wg}$  = subsurface flow recession coefficient, (1/T);
- $C_{ws}$  = surface runoff recession coefficient, (1/T);
- $S_{wgt}$  = threshold value for groundwater storage within the small watershed above which groundwater at the small watershed contributes to surface flow, ( $L^3$ ).

### 3.7. Solution of the System of Equations

Simulation of the hydrological processes that are included in IWFEM requires the simultaneous solution of three equations; namely groundwater flow equation, stream flow equation and the lake storage equation. Spatial and temporal discretization of the groundwater, stream and lake equations result in a system of non-linear algebraic equations where the unknowns are the groundwater head ( $h^{t+1}$ ), stream surface elevation ( $h_s^{t+1}$ ) and the lake elevation ( $h_{lk}^{t+1}$ ) at the present time step. This system of equations can be represented in a matrix form as

$$[X] \{ \mathbb{H}^{t+1} \} + \{ F \} = 0 \quad (3.95)$$

In (3.95),  $\{ \mathbb{H}^{t+1} \}$  is the vector of unknowns that is generated by augmenting the unknown groundwater heads, stream surface elevations and the lake surface elevations at the present time step:

$$\{\mathbb{H}^{t+1}\} = \left\{ \begin{array}{c} \mathbf{h}_{s_1}^{t+1} \\ \vdots \\ \mathbf{h}_{s_{NR}}^{t+1} \\ \mathbf{h}_{lk_1}^{t+1} \\ \vdots \\ \mathbf{h}_{lk_{NLK}}^{t+1} \\ \mathbf{h}_1^{t+1} \\ \vdots \\ \mathbf{h}_{N_L \cdot N}^{t+1} \end{array} \right\} \quad (3.96)$$

where

NR = total number of stream nodes, (dimensionless);

NLK = total number of lakes, (dimensionless);

$N_L$  = number of aquifer layers, (dimensionless);

N = number of finite element nodes in an aquifer layer, (dimensionless).

Therefore, equation (3.95) represents a system of  $NR + NLK + N_L \cdot N$  equations.

The first NR equations are expressed as in (3.76), the  $(NR+1)^{th}$  to  $(NR+NLK)^{th}$  equations are expressed as in (3.77), and the rest of the equations are given in (3.10).

IWFM uses Newton-Raphson method in order to linearize the equation set (3.95).

This method utilizes the Taylor series expansion of (3.95) around starting values of unknowns and truncates the second and higher order terms. Using the Newton-Raphson method, the  $r^{th}$  equation of (3.95),  $\mathbb{F}_r$ , can be expressed as (Huyakorn and Pinder, 1983)

$$\sum_{i=1}^{NR+NLK+N_L \cdot N} \left( \frac{\partial \mathbb{F}_r}{\partial \mathbb{H}_i^{t+1}} \right)^k \left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1} = \mathbb{F}_r^k \quad (3.97)$$

where

$$\mathbb{F}_r = \mathbb{F}_r \left\{ \mathbb{H}_1, \mathbb{H}_2, \dots, \mathbb{H}_{NR+NLK+N_L \cdot N-1}, \mathbb{H}_{NR+NLK+N_L \cdot N} \right\} \quad (3.98)$$

and

$$\left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1} = \left( \mathbb{H}_i^{t+1} \right)^{k+1} - \left( \mathbb{H}_i^t \right)^{k+1} \quad (3.99)$$

In (3.97)-(3.99),  $k$  is the iteration level. For  $r=1, \dots, NR+NLK+N_L \cdot N$  equation (3.97) represents a system of linear equations that needs to be solved for  $\left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1}$ . This system of equation can be expressed in matrix notation as

$$\left[ \mathbb{X}^k \right] \left\{ \left( \Delta \mathbb{H}^{t+1} \right)^{k+1} \right\} = \left\{ \mathbb{F}^k \right\} \quad (3.100)$$

The aim is to estimate the unknown values of  $\mathbb{H}_i^{t+1}$ , compute the components of the matrix  $\left[ \mathbb{X}^k \right]$  and the vector  $\left\{ \mathbb{F}^k \right\}$  and solve the equation system (3.100) for  $\left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1}$ . The  $L_2$ -norm of the difference vector is used to check the convergence:

$$\left\| \left( \Delta \mathbb{H}^{t+1} \right)^{k+1} \right\|_2 = \sqrt{\sum_{i=1}^{NR+NLK+N_L \cdot N} \left[ \left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1} \right]^2} \quad (3.101)$$

If the  $L_2$ -norm given in (3.101) is not smaller than a pre-specified tolerance, the unknown values of  $\mathbb{H}_i^{t+1}$  are re-estimated using (3.99), and the procedure is continued

until convergence is achieved. The components of  $\left[ \mathbb{X}^k \right]$  and  $\left\{ \mathbb{F}^k \right\}$  are listed in Appendix A.

The coefficient matrix  $\left[ \mathbb{X}^k \right]$  in (3.100) is a sparse matrix. The level of its sparseness depends on the numbering of groundwater, stream and lake nodes. IWFM uses either the over-relaxation method combined with the Jacobi method (Gerald and Wheatley, 1994), or a modified pre-conditioned conjugate gradient method (Dixon et. al, 2010 and 2011) to solve the equation system in (3.100), iteratively. The over-relaxation method will be explained in this document. The details of the modified pre-conditioned conjugate gradient method are explained by Dixon et. al (2010, 2011).

The over-relaxation method starts with an initial estimate to the solution vector,

$\left\{ \left[ \left( \Delta \mathbb{H}^{t+1} \right)^{k+1} \right]^r \right\}$ , where  $r$  is the iteration counter for the iterative solution of (3.100). It

should be noted that the iteration counter  $r$  is different than the iteration counter  $k$ . Index  $k$  is the iteration counter for Newton-Raphson method which is used to solve a system of non-linear equations. On the other hand, index  $r$  is the iteration counter for the matrix inversion method that is used to solve the matrix equation that is generated by a single iteration of the Newton-Raphson method.

With initial estimates, the  $i^{\text{th}}$  equation of (3.100) can be solved for the new estimate of the unknown value:

$$\left[ \left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1} \right]^{r+1} = \frac{\mathbb{F}_i^k - \sum_{\substack{j=1 \\ j \neq i}}^{NR+NLK+N_L \cdot N} \mathbb{X}_{i,j}^k \left[ \left( \Delta \mathbb{H}_j^{t+1} \right)^{k+1} \right]^r}{\mathbb{X}_{i,i}^k} \quad (3.102)$$

Equation (3.102) is used to compute all the components of the solution vector, and the convergence between the initial estimates and the newly computed values is checked:

$$\sqrt{\sum_i \left( \left[ \left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1} \right]^{r+1} - \left[ \left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1} \right]^r \right)^2} \leq \varepsilon \quad (3.103)$$

where  $i = 1, \dots, NR + NLK + N_L \cdot N$ . If the convergence criteria given in (3.103) is not satisfied for all unknowns, the over-relaxation method is used to update their values:

$$\begin{aligned} & \left[ \left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1} \right]^{r+1*} \\ & = \left[ \left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1} \right]^r + \beta \left\{ \left[ \left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1} \right]^{r+1} - \left[ \left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1} \right]^r \right\} \end{aligned} \quad (3.104)$$

where  $i = 1, \dots, NR + NLK + N_L \cdot N$ . In (3.104),  $\left[ \left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1} \right]^{r+1*}$  is the new estimate

that will be used in the next iteration instead of  $\left[ \left( \Delta \mathbb{H}_i^{t+1} \right)^{k+1} \right]^{r+1}$ , and  $\beta$  is the relaxation

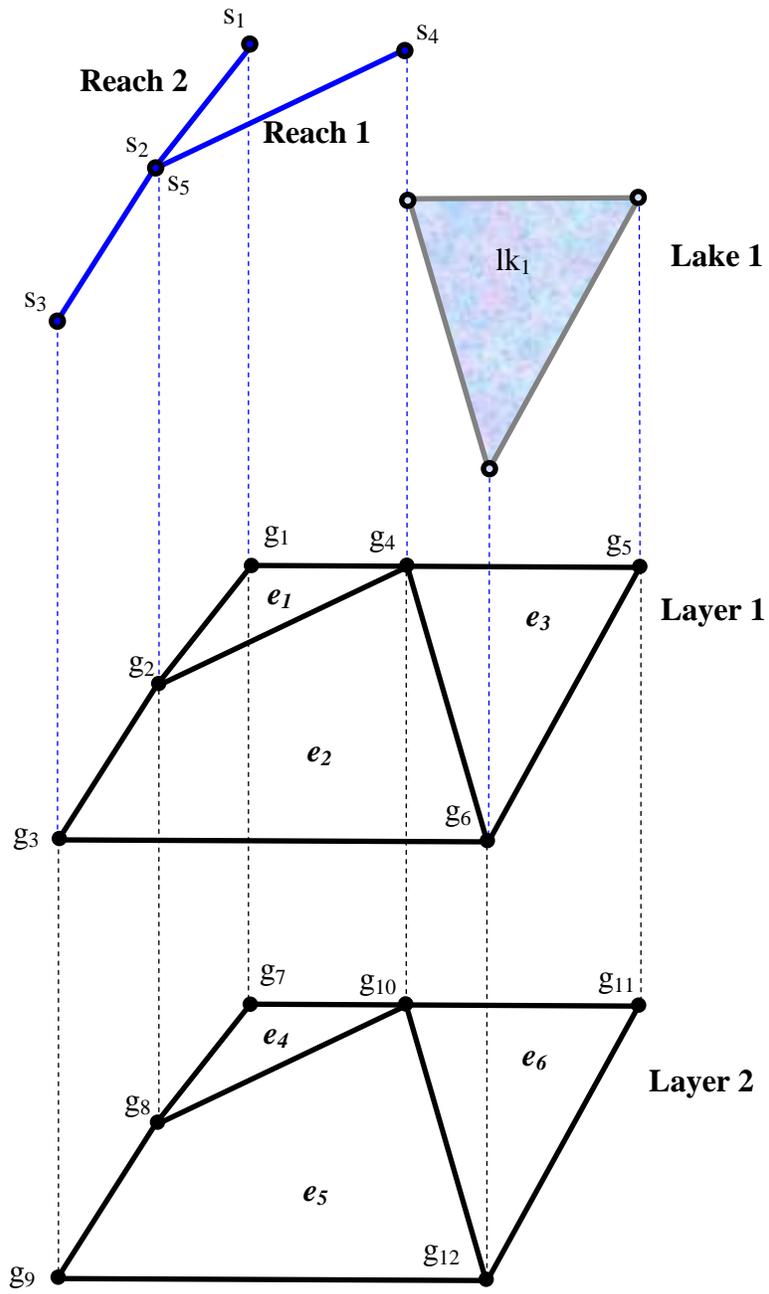

parameter.

### 3.7.1. Compressed Storage of Matrices

In order to decrease the computer storage requirements, IWFM only stores the non-zero components of the coefficient matrix  $\left[ \mathbb{X}^k \right]$  (see Appendix A for expressions of non-zero components). These values are stored in a one-dimensional array in order to decrease the array access times and, hence, computer run times.

Storing only some of the components of a two-dimensional matrix in a one-dimensional array requires the storage of locations of these components to be able to reconstruct the matrix. The location of a non-zero component in the matrix  $\left[ \mathbb{X}^k \right]$  depends on the node numbering in the model and the stream, lake and groundwater nodes that interact with each other. As an example, consider Figure 3.7 where a hypothetical model domain with 2 aquifer layers is represented by 6 finite elements, 12 groundwater nodes, 5 stream nodes and 1 lake. Therefore, there are a total of 18 unknown parameters whose values are computed by solving the stream, lake and groundwater conservation equations simultaneously.

A stream node is connected to a groundwater node and other stream nodes that are located directly upstream of it; a lake is connected to multiple groundwater nodes; a groundwater node is connected to an upper groundwater node, a lower groundwater node, surrounding groundwater nodes and a stream node or a lake. The node connection scheme for the system shown in Figure 3.7 is tabulated in Table 3.1. The global

**Figure 3.7** Hypothetical model domain

unknown numbers are printed in bold and the corresponding stream node, groundwater node or lake numbers are printed in parentheses.

Table 3.1 lists the locations of the non-zero components of the coefficient matrix  $[\mathbb{X}^k]$ . An “unknown number-connecting node” pair represents the row and column numbers of a non-zero component. An “unknown number-unknown number” pair represents a component located on the diagonal of the matrix. For instance, an unknown number of 10 and connecting node number 4 represents the component in the 10<sup>th</sup> row and the 4<sup>th</sup> column of the coefficient matrix (see Table 3.1). This component is the derivative of the conservation equation written at groundwater node 4 with respect to the stream surface elevation at stream node 4.

Table 3.1 lists the global unknown numbers and the connecting nodes as they are stored in IWFEM. For some groundwater nodes, a value of zero appears for upper or lower connecting groundwater nodes. When IWFEM encounters a value of zero, this means that there is no upper or lower aquifer layer for the groundwater node being considered.

IWFEM uses a one-dimensional array,  $\{JND\}$ , to store the information given in Table 3.1. Another one-dimensional array,  $\{NJD\}$ , is used to store the index numbers in  $\{JND\}$ , where information for a node, i.e. for a row of  $[\mathbb{X}^k]$ , starts:

$$\{JND\} = \left\{ \begin{array}{cccc} \text{Unknown 1} & \text{Unknown 2} & \text{Unknown 6} & \text{Unknown 18} \\ \left( \text{row 1 of } [\mathbb{X}^k] \right) & \left( \text{row 2 of } [\mathbb{X}^k] \right) & \left( \text{row 6 of } [\mathbb{X}^k] \right) & \left( \text{row 18 of } [\mathbb{X}^k] \right) \\ \underbrace{1,7} & , \underbrace{2,8,1,5} & , \dots, \underbrace{6,10,12,11} & , \dots, \underbrace{18,12,0,16,14,15,17} \end{array} \right\} \quad (3.105)$$

(c) Connecting nodes for groundwater nodes

**Table 3.1** Node connection scheme for the example shown in Figure 3.8

$$\{NJD\} = \{1, 3, \dots, 15, \dots, 96\} \quad (3.106)$$

With the information stored in the arrays  $\{JND\}$  and  $\{NJD\}$ , the coefficient matrix can be reconstructed. For the example shown in Figure 3.7, the coefficient matrix  $[\mathbb{X}^k]$  has a total of 324 ( $= 18 \times 18$ ) components. The above methodology for storing information has a total of 222 components (102 components for  $\{JND\}$ , 18 components for  $\{NJD\}$  and 102 components for the array that stores the actual values of non-zero components of  $[\mathbb{X}^k]$ ). This amounts to around 30% of savings in computer storage requirements even for a small problem as shown in Figure 3.7. For larger problems, savings in storage requirements will be larger.

Another two-dimensional matrix that arises due to the numerical methods used in IWFM is the conductance matrix (see equation (3.10)):

$$AT_{i,j}^{t+1} = \sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} (T^e)^{t+1} \iint_{\Omega^e} \bar{\nabla} \omega_i^e \bar{\nabla} \omega_j^e d\Omega^e \quad (3.107)$$

where  $1 \leq m \leq N_L$  and  $N \cdot (m-1)+1 \leq i, j \leq N \cdot m$ .

The components of  $[AT^{t+1}]$  are stored for each groundwater node. As an example, consider the finite element mesh depicted in Figure 3.7. For elements 1, 2, and 3 of Figure 3.7, the element conductance matrices for the first aquifer layer will have the following structure:

$$\begin{bmatrix} \mathbf{g}_1 & \mathbf{g}_2 & \mathbf{g}_4 \\ \mathbf{AT}_{\mathbf{g}_1, \mathbf{g}_1}^{e1} & \mathbf{AT}_{\mathbf{g}_1, \mathbf{g}_2}^{e1} & \mathbf{AT}_{\mathbf{g}_1, \mathbf{g}_4}^{e1} \\ \mathbf{AT}_{\mathbf{g}_2, \mathbf{g}_1}^{e1} & \mathbf{AT}_{\mathbf{g}_2, \mathbf{g}_2}^{e1} & \mathbf{AT}_{\mathbf{g}_2, \mathbf{g}_4}^{e1} \\ \mathbf{AT}_{\mathbf{g}_4, \mathbf{g}_1}^{e1} & \mathbf{AT}_{\mathbf{g}_4, \mathbf{g}_2}^{e1} & \mathbf{AT}_{\mathbf{g}_4, \mathbf{g}_4}^{e1} \end{bmatrix} \begin{bmatrix} \mathbf{g}_1 \\ \mathbf{g}_2 \\ \mathbf{g}_4 \end{bmatrix} \quad (3.108)$$

$$\begin{bmatrix} \mathbf{g}_2 & \mathbf{g}_3 & \mathbf{g}_6 & \mathbf{g}_4 \\ \mathbf{AT}_{\mathbf{g}_2, \mathbf{g}_2}^{e2} & \mathbf{AT}_{\mathbf{g}_2, \mathbf{g}_3}^{e2} & \mathbf{AT}_{\mathbf{g}_2, \mathbf{g}_6}^{e2} & \mathbf{AT}_{\mathbf{g}_2, \mathbf{g}_4}^{e2} \\ \mathbf{AT}_{\mathbf{g}_3, \mathbf{g}_2}^{e2} & \mathbf{AT}_{\mathbf{g}_3, \mathbf{g}_3}^{e2} & \mathbf{AT}_{\mathbf{g}_3, \mathbf{g}_6}^{e2} & \mathbf{AT}_{\mathbf{g}_3, \mathbf{g}_4}^{e2} \\ \mathbf{AT}_{\mathbf{g}_6, \mathbf{g}_2}^{e2} & \mathbf{AT}_{\mathbf{g}_6, \mathbf{g}_3}^{e2} & \mathbf{AT}_{\mathbf{g}_6, \mathbf{g}_6}^{e2} & \mathbf{AT}_{\mathbf{g}_6, \mathbf{g}_4}^{e2} \\ \mathbf{AT}_{\mathbf{g}_4, \mathbf{g}_2}^{e2} & \mathbf{AT}_{\mathbf{g}_4, \mathbf{g}_3}^{e2} & \mathbf{AT}_{\mathbf{g}_4, \mathbf{g}_6}^{e2} & \mathbf{AT}_{\mathbf{g}_4, \mathbf{g}_4}^{e2} \end{bmatrix} \begin{bmatrix} \mathbf{g}_2 \\ \mathbf{g}_3 \\ \mathbf{g}_6 \\ \mathbf{g}_4 \end{bmatrix} \quad (3.109)$$

$$\begin{bmatrix} \mathbf{g}_4 & \mathbf{g}_6 & \mathbf{g}_5 \\ \mathbf{AT}_{\mathbf{g}_4, \mathbf{g}_4}^{e3} & \mathbf{AT}_{\mathbf{g}_4, \mathbf{g}_6}^{e3} & \mathbf{AT}_{\mathbf{g}_4, \mathbf{g}_5}^{e3} \\ \mathbf{AT}_{\mathbf{g}_6, \mathbf{g}_4}^{e3} & \mathbf{AT}_{\mathbf{g}_6, \mathbf{g}_6}^{e3} & \mathbf{AT}_{\mathbf{g}_6, \mathbf{g}_5}^{e3} \\ \mathbf{AT}_{\mathbf{g}_5, \mathbf{g}_4}^{e3} & \mathbf{AT}_{\mathbf{g}_5, \mathbf{g}_6}^{e3} & \mathbf{AT}_{\mathbf{g}_5, \mathbf{g}_5}^{e3} \end{bmatrix} \begin{bmatrix} \mathbf{g}_4 \\ \mathbf{g}_6 \\ \mathbf{g}_5 \end{bmatrix} \quad (3.110)$$

In equations (3.108)-(3.110), the time step index t+1 is dropped for simplicity. Element conductance matrices will have the similar structure for other layers of the aquifer system except that the indexing will change with the changing node numbers. The component values are also likely to be different for each layer since the transmissivities at a vertical cross-section may differ. IWFM stores the following components of matrices (3.108)-(3.110) in an augmented one-dimensional array:

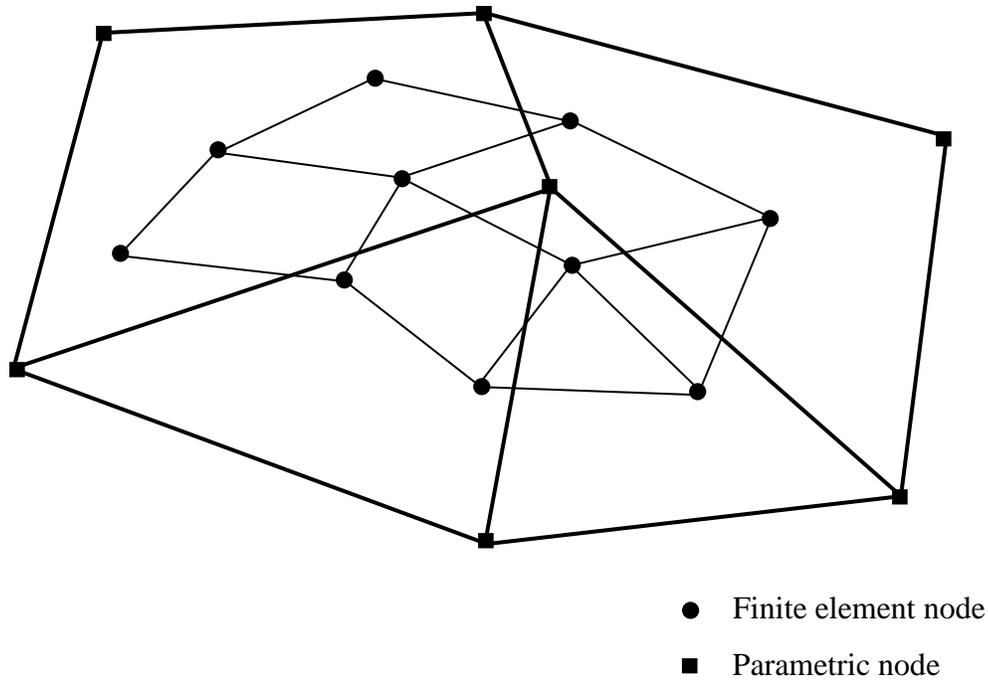

head value) at each finite element node. IWFM allows the user to define these values through input files.

However, in most practical applications it is not possible to compile the required parameter values for each node of the finite element mesh. Instead, sets of values measured at a small number of observation sites will be available. Furthermore, the locations of these sites will generally not coincide with any of the nodes of the finite element mesh. To overcome this problem, IWFM allows the user to interpolate the parameter values measured at a small number of locations in order to specify values at the nodes of the finite element mesh. The interpolation is based purely on the geographic locations of the observation sites and the finite element nodes. IWFM uses the term *parametric node* for an observation site in order to differentiate it from a finite element node. A collection of parametric nodes forms the *parametric mesh* as opposed to finite element mesh. A parametric mesh may consist of triangular and/or quadrilateral elements (Figure 3.8). An individual parametric mesh can be used for specification of parameter values at finite element nodes of the entire model domain, or several parametric meshes covering smaller portions of the model domain can be utilized.

The mathematical theory underlying the interpolation technique used in IWFM is similar to that of the finite element method discussed earlier in this chapter. The continuous function of a particular parameter over a parametric element can be approximated by the discrete parameter values defined at the parametric nodes as

$$\phi_{ep}(x, y) \cong \hat{\phi}_{ep}(x, y) = \sum_{i=1}^{N_{ep}} \phi_i^{ep} \omega_i^{ep}(x, y) \quad (3.113)$$

where

**Figure 3.8** An example of parametric and finite element mesh system

$\phi_{ep}(x, y)$  = continuous function of a particular aquifer parameter over the parametric element  $ep$ ;

$\hat{\phi}_{ep}(x, y)$  = approximation for  $\phi_{ep}(x, y)$ ;

$\phi_i^{ep}$  = parameter value at parametric node  $i$ ;

$\omega_i^{ep}(x, y)$  = element shape function defined for the parametric node  $i$ ;

$N_{ep}$  = number of parametric nodes that define a parametric element; 3 for a triangular element and 4 for a quadrilateral element.

The expressions for element shape functions,  $\omega_i^{ep}(x, y)$ , are given in section 3.1.1 for both linear triangular and linear quadrilateral elements. These expressions are also

valid for parametric linear elements. Equation (3.113) reveals that, for a finite element node that is located in a parametric element, the parameter value at the finite element node can be expressed as a linear algebraic function of the parameter values at the surrounding parametric nodes. If the coordinates of the finite element node is given as  $(x_o, y_o)$ , the parameter value at this node can be expressed by equation (3.113) as

$$\hat{\phi}(x_o, y_o) = \phi_j^{ef} = \sum_{i=1}^{N_{ep}} \phi_i^{ep} \omega_i^{ep}(x_o, y_o) \quad (3.114)$$

where  $\phi_j^{fe}$  is the value of the parameter at the finite element node  $j$ . Therefore,  $\omega_i^{ep}(x_o, y_o)$  are the interpolating coefficients corresponding to each of the surrounding parametric nodes.

The shape functions for a linear quadrilateral element are defined in  $(\xi, \eta)$  space instead of  $(x, y)$  space as given in equations (3.20)-(3.23). Therefore, it is necessary to convert the coordinates of the finite element node  $(x_o, y_o)$  into  $(\xi_o, \eta_o)$  in order to define the interpolating coefficients for a quadrilateral parametric element. This can be achieved by first solving equations (3.17) and (3.18) for  $\xi(x, y)$  and  $\eta(x, y)$ , simultaneously and substituting  $x_o$  and  $y_o$  into the resulting solutions to obtain  $\xi_o$  and  $\eta_o$ .

## **4. Demand and Supply**

An important objective of IWFM is to simulate the water supply to meet a specified agricultural and urban demand. This chapter explains the computation of urban and agricultural demand, simulation of water supply, and the water allocation process with respect to different land use types.

### **4.1. Land Use**

IWFM has the capability to model flow processes over agricultural, urban, native and riparian lands. The land use areas must be specified for every element within the model domain for the purpose of simulating unsaturated flow on an elemental basis. The area of each crop, as well as urban, native and riparian lands are to be specified for each subregion in order to compute runoff, infiltration, soil moisture, and deep percolation based on land use information.

In a hydrologic basin, the extent of the agricultural and urban areas defines a specific water demand that needs to be met by stream flow diversions and groundwater pumping. Diverting stream flows and extracting water from the groundwater storage, and distributing it over the modeled area to meet the water demand, changes the natural runoff characteristics of the basin. The approach taken in IWFM to model hydrologic processes based on each land use type plays a key role in the effectiveness of IWFM as a planning model. With this approach, demand is computed or specified for agricultural and urban areas separately. The allocation of surface water diversions and pumping to agricultural and urban lands is determined by defining the fraction of the specified

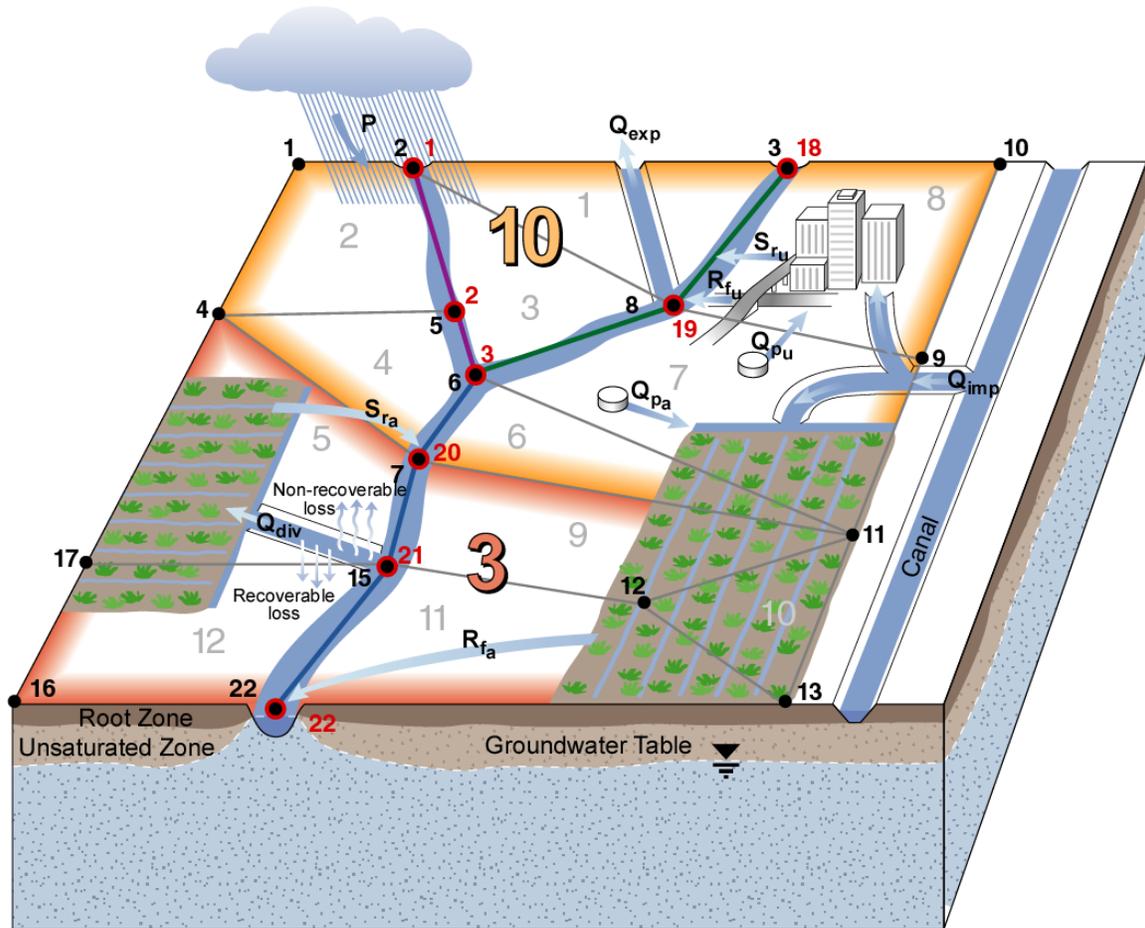

diversion and pumping that is intended for irrigation purposes, and designating the remaining portion for urban use. Once stream flows are simulated, actual surface water diversions are computed based on the available stream flows, and applied to agricultural and urban areas according to user specified fractions to meet the appropriate demands. Groundwater pumping and recharge can be specified in several ways, but IWFM has the functionality to pump or recharge by element, based on the relative agricultural and urban areas within an element. Similar to surface water diversions, groundwater pumping can also be distributed among agricultural and urban lands with respect to predefined fractions.

## **4.2. Agricultural and Urban Water Demands**

Agricultural and urban water demands can either be computed dynamically or specified by the user as input data. Both agricultural and urban water demands are computed at each finite element based on the respective land-use area, soil and climatic conditions, and crop management practices. A detailed explanation of how these demands are computed is given in DWR (2012) and will not be repeated in this document.

## **4.3. Supply**

Figure 4.1 illustrates the sources of water supply in IWFM, as well as the allocation of water for different uses. Surface water diversions and groundwater pumping are the two processes that define prime water supply. Re-use of return flow can

also be considered as a source of water. The surface water and groundwater supply as well as re-used return flow are determined by the simulation of stream flows, groundwater flow and return flow of applied water.

#### **4.3.1. Surface Water Diversions and Deliveries**

Each surface water diversion modeled in IWFMM is associated with a stream node and may be limited with a user-specified maximum diversion amount that represents the capacity of the conveyance system. A surface water diversion can be delivered to an element, to a group of elements, to a subregion or it can be exported outside the model domain. Specified for every diversion is the amount of water used for irrigation purposes and to meet the urban water demand. IWFMM currently computes the actual diversion and delivery amounts, and reports any diversion shortages or surplus. The actual amount of water available for delivery is based on the simulated stream flows.

The conveyance losses for each diversion are specified as a fraction of the total diversion. Recoverable losses are one type of conveyance loss modeled in IWFMM. This type of loss is termed “recoverable”, since the water is assumed to eventually percolate to the groundwater, and become part of groundwater flow. A non-recoverable loss is the other type of conveyance loss modeled in IWFMM. This water leaves the system through evaporation. Under circumstances where shortages occur, recoverable and non-recoverable losses are adjusted to reflect the actual amount of water that is diverted. Based on the above discussion, applied water to agricultural and urban lands at the

destination of the delivery (i.e. a single element, a group of elements or a subregion) are computed in IWFM as

$$AW_{ag,i}^{div} = Q_{div,i} (1 - R_{L_i} - NR_{L_i}) f_{ag_i} \quad (4.1)$$

$$AW_{u,i}^{div} = Q_{div,i} (1 - R_{L_i} - NR_{L_i}) (1 - f_{ag_i}) \quad (4.2)$$

where

$i$  = index for diversion number, (dimensionless);

$AW_{ag,i}^{div}$  = actual amount of water delivered to agricultural lands from diversion number  $i$ , ( $L^3/T$ );

$AW_{u,i}^{div}$  = actual amount of water delivered to urban lands from diversion number  $i$ , ( $L^3/T$ );

$Q_{div,i}$  = stream diversion at diversion number  $i$  before conveyance losses, ( $L^3/T$ );

$R_{L_i}$  = fraction of the stream diversion that becomes recoverable loss at diversion number  $i$ , (dimensionless);

$NR_{L_i}$  = fraction of the stream diversion that becomes non-recoverable loss at diversion number  $i$ , (dimensionless);

$f_{ag_i}$  = fraction of the diversion at diversion number  $i$  that is delivered to the agricultural lands, (dimensionless).

$AW_{ag}^{div}$  and  $AW_u^{div}$  are the total agricultural and urban water deliveries, respectively, at the destination of the delivery. IWFM computes water demands for each individual crop and urban land at the finite element level. To further distribute the

deliveries to urban lands and individual crops at element level, IWFM uses the computed water demands. Each land-use type receives water in proportion to their water demands to the total water demand in the delivery destination. For instance, if the delivery goes to a single element, then IWFM distributes the agricultural water among the crops in the destination element with respect to their water demands. Urban water goes to the urban lands in that element without modification. If the delivery goes to a group of elements or a subregion, then IWFM distributes agricultural and urban water deliveries to individual elements first according to the fraction of the water demand in each element to the total water demand in the group of elements or the subregion. Once the element-level delivery is computed, it is distributed among individual crops in that element according to the water demands of each crop. If for any reason, the agricultural or urban water demand in the delivery destination is zero (i.e. if there is water surplus), then IWFM distributes the water delivery with respect to the area of individual crops or urban lands.

IWFM has the functionality to model bypass flows, which serves as a method of routing flow to avoid flooding. The model simulates flow through a bypass canal by diverting water from a stream node and adding the diverted water to another downstream node. When simulating bypass flows, conveyance losses are accounted for by assigning percentages of the bypass flow to recoverable and non-recoverable losses occurring in the bypass canal.

#### **4.3.2. Groundwater Pumping and Recharge**

IWFM has the functionality to simulate groundwater pumping and recharge by

well location or on an elemental basis. Pumping is a source of water supply, whereas recharge is the replenishment of water to the aquifer system during model simulation. The only difference computationally between pumping and recharge in IWFM is the sign convention.

#### ***4.3.2.a. Pumping and Recharge at Well Locations***

IWFM has the capability to simulate pumping and recharge from well logs. Pumping and recharge at specific well locations require the user to input all simulated well locations in (x,y) coordinates. Based on the well location, IWFM identifies the finite element that contains the location of the well and computes the interpolating coefficients (refer to section 3.8 for the interpolation method) to distribute the pumping amount to the groundwater nodes that correspond with the element.

Since IWFM has the capability to model multiple layers, the vertical distribution of pumping from each layer must be computed. The vertical distribution of pumping to each aquifer layer is proportional to the length of the well screen and the transmissivity of the aquifer layer:

$$Q_{P_m} = Q_{P_T} \frac{f_m T_m}{\sum_{i=1}^{N_L} f_i T_i} \quad (4.3)$$

where

$Q_{P_m}$  = pumping from aquifer layer m, (L<sup>3</sup>/T);

$Q_{P_T}$  = total pumping at the well, (L<sup>3</sup>/T);

- f = fraction of vertical distribution for each layer, (dimensionless);
- T = transmissivity, (L<sup>2</sup>/T);
- N<sub>L</sub> = total number of aquifer layers, (dimensionless).

The Kozeny equation is used to define the fraction of vertical distribution, f, which accounts for the effect of partial penetration of a well in an aquifer layer (Driscoll, 1986):

$$f_m = \ell_s \left[ 1 + 7 \sqrt{\frac{r}{2b\ell_s}} \cos\left(\frac{\pi\ell_s}{2}\right) \right] \quad (4.4)$$

where

- f<sub>m</sub> = fraction of pumping from aquifer layer m, (dimensionless);
- ℓ<sub>s</sub> = well screen length as a fraction of the aquifer thickness, (dimensionless);
- r = well radius, (L);
- b = aquifer thickness, (L).

#### ***4.3.2.b. Elemental Distribution of Pumping and Recharge***

It is sometimes impossible to locate every well in the modeled area and access the pumping records. Instead, average values for the pumping or recharge amounts may be available for a section of the modeled area. For this reason, IWFM has the functionality to distribute regional pumping/recharge values to elements when they are specified for areas containing well locations that are not defined in terms of specific coordinates. The distribution of pumping to elements can be done in one of the following five ways in IWFM:

- (i) Pumping can be distributed based on a factor specified for each element associated with the total pumping,  $P_T$ :

$$Q_{P_e} = f_e Q_{P_T} \quad (4.5)$$

where

$Q_{P_e}$  = pumping at element  $e$ , ( $L^3/T$ );

$Q_{P_T}$  = total pumping from an area, ( $L^3/T$ );

$f_e$  = factor that defines the amount of pumping allocated to element  $e$ ,  
(dimensionless).

- (ii) The second option when distributing pumping to an element is to define the pumping with respect to the area of each element relative to the area that corresponds to the total pumping value and a user defined fraction:

$$Q_{P_e} = \frac{Q_{P_T} f_{i=e} A_{i=e}}{\sum_{i=1}^n (f_i \times A_i)} \quad (4.6)$$

where

$f_i$  = fraction that defines the amount of pumping from element  $i$ ,  
(dimensionless);

$A_i$  = area of element  $i$ , which is also associated with the total pumping  
 $Q_{P_T}$ , ( $L^2$ );

$n$  = number of elements that the total pumping,  $Q_{P_T}$  is distributed to,  
(dimensionless).

- (iii) The third option is based on the relative amount of agricultural and urban area in an element with respect to the agricultural and urban areas in all other elements that the total pumping,  $Q_{P_T}$  is distributed to:

$$Q_{P_e} = \frac{Q_{P_T} f_{i=e} (A_{i=e,ag} + A_{i=e,ur})}{\sum_{i=1}^n [f_i \times (A_{i,ag} + A_{i,ur})]} \quad (4.7)$$

where

$A_{i,ag}$  = agricultural area within element i, ( $L^2$ );

$A_{i,ur}$  = urban area within element i, ( $L^2$ ).

- (iv) The elemental pumping distribution can be computed based on the relative amount of agricultural area in an element with respect to the agricultural areas in all other elements that are assigned pumping from  $Q_{P_T}$ .

$$Q_{P_e} = \frac{Q_{P_T} f_{i=e} A_{i=e,ag}}{\sum_{i=1}^n (f_i \times A_{i,ag})} \quad (4.8)$$

- (v) The final option to be discussed is the elemental distribution of pumping with respect to the relative amount of urban area in an element to the urban areas of all other elements that are assigned a portion of the total pumping ( $Q_{P_T}$ ):

$$Q_{P_e} = \frac{Q_{P_T} f_{i=e} A_{i=e,ur}}{\sum_{i=1}^n (f_i \times A_{i,ur})} \quad (4.9)$$

For simplicity, the computations described in equations (4.5) - (4.9) are defined in terms of pumping. However, recharge is computed in the same manner as pumping, with

the exception of the sign convention.

Similar to applied water from diversions, pumping is also used to meet agricultural and urban water demands at a single element, at a group of elements or at a subregion. It can also be exported outside the model area. Pumping can be limited with user-specified maximum amounts representing the pump capacities. Similar to diversions, well and elemental pumping are proportioned between the agricultural and urban lands based on user-specified fractions:

$$AW_{ag,i}^P = Q_{P,i} f_{ag_i} \quad (4.10)$$

$$AW_{u,i}^P = Q_{P,i} (1 - f_{ag_i}) \quad (4.11)$$

where

$i$  = index for pumping, (dimensionless);

$AW_{ag,i}^P$  = actual amount of water supplied to agricultural lands from pump number  $i$ , ( $L^3/T$ );

$AW_{u,i}^P$  = actual amount of water supplied to urban lands from pump number  $i$ , ( $L^3/T$ );

$Q_{P,i}$  = actual pumping at pump number  $i$ , ( $L^3/T$ );

$f_{ag_i}$  = fraction of the pumping that is supplied to the agricultural lands from pump number  $i$ , (dimensionless).

IWFM uses the same methods as for the diversions to distribute pumping to individual crops and urban lands at each element at the delivery destination once  $AW_{ag,i}^P$

and  $AW_{u,i}^p$  are computed.

#### ***4.3.2.c. Computation of Pumping at Drying Wells***

IWFM strives not only to compute groundwater heads and stream flows accurately but also to define the actual amount of water supply that is distributed over the model area to meet the water demand. During pumping, if a well dries during a time step the groundwater head will be computed as being less than the elevation of the bottom of the deepest aquifer that the well is drilled to. However, this is not possible since IWFM only models the saturated groundwater flow. Furthermore, it is important to identify the exact time that the well dries in order to compute the total amount of water that is actually pumped from the well. In general, this is an inverse problem and it requires the solution of the inverse of the groundwater conservation equation. In order to address these two problems, IWFM uses an iterative method.

If the groundwater head at a node falls below the bottom of the aquifer due to pumping during a time step, IWFM enters the mode of iterative inverse-problem solution. The estimated pumping is calculated as

$$\left(Q_{P_i}^{t+1}\right)^{k+1} = \frac{\left(Q_{P_i}^{t+1}\right)^k + \left(Q_{P_i}^{t+1}\right)^{k'}}{2} \quad (4.12)$$

where

$$\left(Q_{P_i}^{t+1}\right)^k = \begin{cases} \left(Q_{P_i}^{t+1}\right)^k - \frac{(z_{k_i} - h_i^{t+1})S_{y_i} A_i}{\Delta t} & \text{if } h_i^{t+1} \leq z_{k_i} \\ \min \left[ \frac{(h_i^{t+1} - z_{k_i})S_{y_i} A_i}{\Delta t}, \left(Q_{P_i}^{t+1}\right)^{\text{req}} \right] & \text{if } h_i^{t+1} > z_{k_i}; \left(Q_{P_i}^{t+1}\right)^k < \left(Q_{P_i}^{t+1}\right)^{\text{req}} \end{cases} \quad (4.13)$$

$i$  = finite element node at which pumping occurs, (dimensionless);

$\left(Q_{P_i}^{t+1}\right)^k$  = pumping rate at node  $i$ , at the  $k^{\text{th}}$  iteration level, ( $L^3/T$ );

$\left(Q_{P_i}^{t+1}\right)^{k+1}$  = pumping rate at node  $i$ , at the  $(k+1)^{\text{th}}$  iteration level, ( $L^3/T$ );

$\left(Q_{P_i}^{t+1}\right)^{\text{req}}$  = required pumping rate at node  $i$  specified by the user, ( $L^3/T$ );

$h_i$  = groundwater head at node  $i$ , (L);

$z_{k_i}$  = elevation of the bottom of the aquifer at node  $i$ , (L);

$S_{y_i}$  = specific yield at node  $i$ , (dimensionless);

$A_i$  = area associated with node  $i$ , ( $L^2$ );

$\Delta t$  = length of time step, (T);

$t$  = index for time step, (dimensionless);

$k$  = iteration level, (dimensionless).

The iteration is stopped when the ratio of the difference between the two pumping rates from consecutive iteration levels to the pumping rate at the previous iteration level is smaller than a tolerance value:

$$\left| \frac{\left(Q_{P_i}^{t+1}\right)^{k+1} - \left(Q_{P_i}^{t+1}\right)^k}{\left(Q_{P_i}^{t+1}\right)^k} \right| \leq \varepsilon \quad (4.14)$$

Estimating  $Q_{P_i}^{t+1}$  iteratively results in a pumping rate that will drawdown the groundwater head at a well to the elevation of the bottom of the aquifer. Once the pumping rate is computed, it is multiplied by the time step length,  $\Delta t$ , to compute the actual volume of pumping that is supplied to urban and agricultural lands.

### 4.3.3. Re-use of Irrigation Water

Re-used irrigation water is another water supply in addition to the prime water (i.e. irrigation water before the application of re-used water) that is delivered to the fields in terms of groundwater pumping or surface water diversions. IWFM simulates only the re-use of return flow. The agricultural return flow computed by IWFM is assumed to be the net return flow after the user-specified portion of the initial return flow is re-used. IWFM allows the user to direct the net return flow from one element to another element, to another subregion or to a stream node. All these options represent different types of re-use that may take place in the modeled boundary.

When the net-return flow from an element is directed to a downstream element, IWFM treats this flow as a separate water supply to meet the agricultural and urban water demands in the destination element. When the net return flow from an element is directed to a subregion, IWFM distributes this flow among the elements of the destination subregion with respect to the water demand at each element and again treats it as a

separate water supply. Finally, in the case that the net return flow is directed to a stream node, it contributes to the stream flow and can be diverted by downstream diverters.

#### **4.3.4. Agricultural Water Use**

Agricultural water use is the amount of the agricultural water demand that can be met by the simulated water supply. The total amount of water delivered to agricultural lands from surface water diversions and pumping is

$$AW_{ag} = AW_{ag}^{div} + AW_{ag}^p \quad (4.15)$$

where  $AW_{ag}^{div}$  and  $AW_{ag}^p$  are given in equations (4.1) and (4.10), respectively. If the simulated supply equals demand, the agricultural water use is simply the demand that is specified or computed (refer to section 4.2). If simulated water supply is less than the demand, then water use is equal to the water supply. On the other hand, if water supply is larger than the demand, then water use is equal to the demand and the amount of supply in excess of demand contributes to surface runoff, increases the soil moisture in the root zone without being used by the plants, or percolates into the unsaturated zone and groundwater. The water supply is delivered to the appropriate locations based on input that specifies the fraction of each surface water diversion that is to be used for irrigation purposes and the fraction of groundwater pumping to be applied to agricultural lands.

### 4.3.5. Urban Water Use

The total amount of water delivered to the urban lands is

$$AW_u = AW_u^{div} + AW_u^P \quad (4.16)$$

where  $AW_u^{div}$  and  $AW_u^P$  are given in equations (4.2) and (4.11), respectively.

Furthermore, based on the simulated water supply, the amount of water available for indoor and outdoor urban use can be expressed as

$$AW_{u_i} = (AW_u)(\%AW_{u_i}) \quad (4.17)$$

$$AW_{u_o} = AW_u - AW_{u_i} \quad (4.18)$$

where

$$AW_{u_i} = \text{indoor urban water use, (L}^3\text{/T);}$$

$$\%AW_{u_i} = \text{fraction of urban water use specified for indoors, (dimensionless);}$$

$$AW_{u_o} = \text{water applied to outdoor urban areas, (L}^3\text{/T).}$$

If supply equals demand, or the model simulates that the supply meets or exceeds the demand, the total urban water use is the urban water demand itself. However, if the simulated water supply is short of meeting the demand, the urban indoor and outdoor water use values are computed by equations (4.17) and (4.18) based on the available water supply.

## 4.4. Automated Supply Adjustment

An important task in water resources planning studies is to find answers to questions such as if there is enough water supply in the modeled area to meet the

agricultural and urban water demand, and how to operate the pumping and diversion facilities in order to minimize the discrepancy between the supply and demand. In order to achieve this task, the functionality to adjust the surface water diversions and/or pumping automatically has been included in IWFM.

The user can choose some or all of the diversions, pumping or both to be adjusted by IWFM in order to meet the agricultural and urban water demand, or to minimize the surplus supply amounts. It should be noted at this point that IWFM does not incorporate optimization techniques in adjusting the water supply. Instead, it tries to distribute the discrepancy between the supply and demand among adjusted diversions or pumping as equally as possible without considering any operation rules. Thus, the resulting diversion and pumping amounts after the adjustment may not be the optimum management of the water resources in terms of financial, environmental and legal constraints. However, these results may help the user to identify hot spots of the modeled region such as streams and pumping locations that may be utilized when there is a shortage of supply, or diversion and pumping locations that constantly fail to produce required amounts of water supply.

In IWFM, the term “adjustment of supply” stands for the procedure of modifying the *required* amount of diversions and pumping to minimize the discrepancy between the water demand and water supply to meet this demand. An adjusted amount of required diversion or pumping does not necessarily mean that that much water can actually be diverted or pumped. For instance, in dry years it may not be possible to divert as much water as the adjusted amount of required diversions. Therefore, it is important to understand that automated adjustment of diversions and pumping will not always

generate a perfect match between the water demand and the actual amount of water supplied to meet this demand.

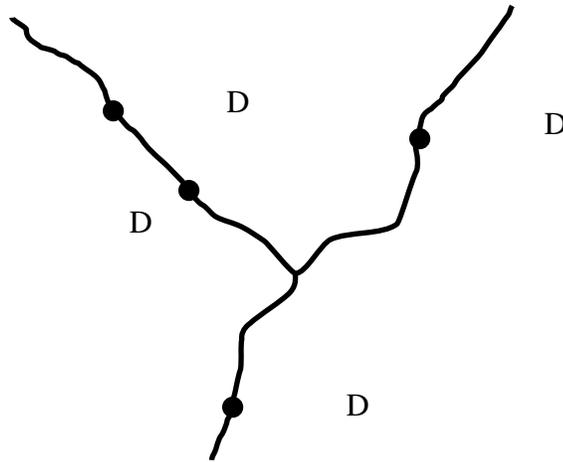

In the following sections, the methods used in adjusting the surface water diversions and pumping are detailed. If the adjustment of both surface water diversions and pumping is desired, then surface water diversions are adjusted first and pumping rates are adjusted second.

#### **4.4.1. Adjustment of Surface Water Diversions**

Surface water diversions are adjusted according to their ranks based on the number of upstream diversion locations. Figure 4.2 shows a hypothetical stream system with four diversion points. These diversion points are ranked as follows:

- *Rank 0:* Diversions 1 and 2 (0 upstream diversion points);
- *Rank 1:* Diversion 3 (1 upstream diversion point, namely diversion 1);
- *Rank 3:* Diversion 4 (3 upstream diversion points, namely diversions 1, 2 and 3).

In the list above, rank 2 is omitted since there are no diversions with two upstream diversion locations. Adjustment of diversions is performed with a multi-step procedure. In the first step, all adjustable diversions (the criteria used to specify a diversion as adjustable is listed below) of all ranks are adjusted and the required amounts of diversions to meet the water demand are computed. If the newly computed diversion requirements can be met, then the adjustment was successful and no further steps are performed. However, if there is still a discrepancy between the actual diversion amounts and the water demand, then the second step of adjustment is performed. In the second

**Figure 4.2** A stream system with 4 diversion locations

step, all adjustable diversions except those with rank 0 are adjusted. At the end of this step if there are still discrepancies between actual diversions and water demands, then IWFM goes to the third step. In the third step, all adjustable diversions except those with ranks 0 and 1 are adjusted. This procedure is performed until the discrepancies are minimized or all ranks of diversions have been adjusted. As an example, IWFM will perform a maximum of three adjustment steps for the hypothetical case shown in Figure 4.2. In the first step all diversions will be adjusted. In the second step diversions 3 and 4, and in the third step only diversion 4 will be adjusted.

As mentioned earlier, agricultural and urban water demands are specified or computed for urban lands and for each crop at every finite element. Each diversion is assigned a delivery destination, either a single element, a group of elements or a subregion, and the amount delivered to the destination is proportioned between urban and agricultural water use based on a fraction specified by the user. Since the final destination of diversions is a finite element regardless of the destination type, the

adjustment of diversions is performed to meet the element level water demand. Each diversion can be adjusted to meet only the agricultural demand, only the urban demand or both at an element.

For the simplicity of explanation, only the procedure that is used to adjust diversions to meet agricultural water demand will be discussed in the following paragraphs. Adjustment of diversions to meet the urban water demand is exactly the same.

First, the discrepancies between the agricultural water demand and the amount of delivery to agricultural lands at an element is computed. If there is a supply shortage, i.e. water demand is larger than the actual delivery to the agricultural lands, the total number of diversions that can be adjusted is computed. When computing the total number of adjustable diversions, the following criteria are used: (i) diverted water is delivered to the element in concern, (ii) diversion originates from a stream node that is not dry (i.e. diversion amount can be increased), (iii) diversion is specified by the user to be adjusted to meet the agricultural water requirement at the element, (iv) the rank of the diversion is greater than or equal to the adjustment step, and (v) the diversion amount before adjustment is less than the maximum amount specified by the user (i.e. diversion amount can be increased). Once the total number of adjustable diversions is computed, the new diversion requirements are calculated by distributing the supply shortage equally among adjustable diversions that deliver water to the specified element. If the adjusted diversion for a specific diversion location is greater than the maximum amount specified by the user, the amount that is above the maximum is further distributed equally among other diversion locations that have not yet reached their own maximum amounts.

With the adjusted diversion requirements, the stream flows are simulated by solving the coupled groundwater-surface water equation set. If the diversion requirements are met, i.e. simulated stream flows are large enough to support the required diversion rates, the adjustment procedure is aborted. Otherwise, above procedure is repeated for the next adjustment step to adjust the diversions with appropriate ranks.

Generally, it is not possible to match the water demand with the actual water supply perfectly when there is a supply shortage. For this reason, IWFEM allows the user to define a tolerance value. If the ratio of the actual supply to the water demand falls below this tolerance value, it is assumed that the supply is satisfactorily close to the water demand and the adjustment procedure is aborted.

If there is a supply surplus, i.e. water demand is less than the actual delivery to the agricultural lands, then it is necessary to decrease the diversion amounts. In this case, the total amount of actual deliveries to the agricultural lands that originate from adjustable diversion locations is computed. The same criteria listed above with the exception of the second (dry stream node) and last (diversion at its maximum) items are used in specifying a diversion as adjustable. The second criterion in this case is redundant since the diversions will be decreased and a dry stream node does not pose a constraint. Similarly, the last item, i.e. the unadjusted diversion being at its maximum, is also no longer a constraint. Once the total amount of actual deliveries from adjustable diversion locations is computed, the required diversion rates are calculated by decreasing each of the adjustable diversion rates with respect to the magnitude of the original diversion rate:

Similar methods are used to adjust deliveries to meet urban water demands. It should be noted that once the deliveries to agricultural and urban lands are adjusted, the

fraction  $f_{ag}$  (see equations (4.1) and (4.2)) that is used to partition the total delivery between agricultural and urban lands also changes.

#### **4.4.2. Adjustment of Pumping**

The adjustment of pumping in order to minimize the discrepancy between the water supply and demand is similar to the adjustment of surface water diversions, except that pumping wells or elements are not ranked the same as diversion points. Instead, pumping requirements are adjusted until the ratio between the actual supply and demand is smaller than the tolerance specified by the user, until further adjustment does not change the required pumping values or until pumping rates reach the maximum amounts specified by the user. The case where required pumping rates no longer change can occur when the required pumping rates are so high that the wells eventually go dry and actual pumping cannot be increased any more. The adjustment can be performed for well pumping as well as elemental pumping.

## Appendix A

### A.1. Components of $\{\mathbb{F}^k\}$ and $[\mathbb{X}^k]$ for Stream Nodes

For  $i = 1, \dots, NR$  :

$$\begin{aligned}
 \diamond \quad \mathbb{F}_i^k &= Q_{s_i} \left[ \left( \mathbb{H}_i^{t+1} \right)^k \right] - \sum_j Q_{s_j} \left[ \left( \mathbb{H}_j^{t+1} \right)^k \right] \\
 &\quad - R_{f_i}^{t+1} - S_{f_i}^{t+1} - Q_{ws_i}^{t+1} - Q_{brs_i}^{t+1} - Q_{td_i}^{t+1} - Q_{lko_i}^{t+1} - Q_{h_i}^{t+1} \\
 &\quad + Q_{b_i}^{t+1} + Q_{div_i}^{t+1} \\
 &\quad + C_{s_i} \left\{ \max \left[ \left( \mathbb{H}_i^{t+1} \right)^k, h_{b_i} \right] - \max \left[ \left( \mathbb{H}_n^{t+1} \right)^k, h_{b_i} \right] \right\} \tag{A.1}
 \end{aligned}$$

$$\begin{aligned}
 \diamond \quad \mathbb{X}_{i,i}^k &= \left( \frac{\partial \mathbb{F}_i}{\partial \mathbb{H}_i^{t+1}} \right)^k \\
 &= \begin{cases} \left( \frac{\partial Q_{s_i} \left( \mathbb{H}_i^{t+1} \right)}{\partial \mathbb{H}_i^{t+1}} \right)^k + C_{s_i} & \text{if } \left( \mathbb{H}_i^{t+1} \right)^k > h_{b_i} \\ \left( \frac{\partial Q_{s_i} \left( \mathbb{H}_i^{t+1} \right)}{\partial \mathbb{H}_i^{t+1}} \right)^k & \text{if } \left( \mathbb{H}_i^{t+1} \right)^k \leq h_{b_i} \end{cases} \tag{A.2}
 \end{aligned}$$

$$\diamond \quad \mathbb{X}_{i,j}^k = \left( \frac{\partial \mathbb{F}_i}{\partial \mathbb{H}_j^{t+1}} \right)^k = - \left( \frac{\partial Q_{s_i}^{t+1} [\mathbb{H}_j^{t+1}]}{\partial \mathbb{H}_j^{t+1}} \right)^k + \left( \frac{\partial Q_{b_i}^{t+1}}{\partial \mathbb{H}_j^{t+1}} \right)^k + \left( \frac{\partial Q_{div_i}^{t+1}}{\partial \mathbb{H}_j^{t+1}} \right)^k \quad (\text{A.3})$$

If the bypass rate,  $Q_{b_i}$ , is specified as constant, then (A.3) can be expressed as

$$\mathbb{X}_{i,j}^k = \begin{cases} - \left( \frac{\partial Q_{s_i}^{t+1} [\mathbb{H}_j^{t+1}]}{\partial \mathbb{H}_j^{t+1}} \right)^k & \text{if } Q_{in_i} \geq Q_{divreq_i}^{t+1} ; Q_i^{**} \geq Q_{breq_i}^{t+1} \\ 0 & \text{otherwise} \end{cases} \quad (\text{A.4})$$

On the other hand, if the bypass rate is specified as a function of stream flow through a rating table (i.e.  $Q_{b_i} = Q_{b_i}(Q_i^{**})$ ) then (A.3) is expressed as

$$\mathbb{X}_{i,j}^k = \begin{cases} \left( \frac{\partial Q_{s_i}^{t+1} [\mathbb{H}_j^{t+1}]}{\partial \mathbb{H}_j^{t+1}} \right)^k \left( \frac{\partial Q_{b_i}^{t+1}}{\partial Q_i^{**}} - 1 \right) & \text{if } Q_{in_i} \geq Q_{divreq_i}^{t+1} \\ 0 & \text{otherwise} \end{cases} \quad (\text{A.5})$$

where

$$Q_{in_i} = \sum_j Q_{s_j} \left[ \left( \mathbb{H}_j^{t+1} \right)^k \right] + R_f^{t+1} + S_f^{t+1} + Q_{ws_i}^{t+1} + Q_{brs_i}^{t+1} + Q_{td_i}^{t+1} + Q_{lko_i}^{t+1} + Q_{h_i}^{t+1} \quad (\text{A.6})$$

$$Q_i^{**} = Q_{in_i} - Q_{div_i}^{t+1} \quad (A.7)$$

$$\diamond \quad \mathbb{X}_{i,n}^k = \left( \frac{\partial \mathbb{F}_i}{\partial \mathbb{H}_n^{t+1}} \right)^k = \begin{cases} -C_{s_i} & \text{if } \left( \mathbb{H}_n^{t+1} \right)^k > h_{b_i} \\ 0 & \text{if } \left( \mathbb{H}_n^{t+1} \right)^k \leq h_{b_i} \end{cases} \quad (A.8)$$

where  $\mathbb{H}_n$  is the groundwater head at the finite element node  $n$  that corresponds to the

stream node  $i$ , and  $NR + NLK + 1 \leq n \leq NR + NLK + N_L \cdot N$ .

## A.2. Components of $\{\mathbb{F}^k\}$ and $[\mathbb{X}^k]$ for Lakes

For  $i = NR + 1, \dots, NR + NLK$  :

$$\begin{aligned} \diamond \quad \mathbb{F}_i^k &= \frac{S_{lk} \left[ \left( \mathbb{H}_i^{t+1} \right)^k \right] - S_{lk} \left[ \mathbb{H}_i^t \right]}{\Delta t} - Q_{brlk}^{t+1} - Q_{inlk}^{t+1} \\ &\quad - \sum_{j=1}^{N_{lk}} \left( P_{lkj}^{t+1} A_{lkj} - EV_{lkj}^{t+1} A_{lkj} - Q_{lkintj}^{t+1} \right) \end{aligned} \quad (A.9)$$

where

$$Q_{lkintj}^{t+1} = C_{lkj} \left\{ \max \left[ \left( \mathbb{H}_j^{t+1} \right)^k, h_{blkj} \right] - \max \left[ \left( \mathbb{H}_n^{t+1} \right)^k, h_{blkj} \right] \right\} \quad (A.10)$$

$$EV_{lkj}^{t+1} A_{lkj} \leq \frac{A_{lkj}}{\Delta t} \max \left[ \mathbb{H}_i^t - h_{blkj}, 0 \right] + P_{lkj}^{t+1} A_{lkj} + \frac{A_{lkj}}{A_{lk}} \left( Q_{brlk}^{t+1} + Q_{inlk}^{t+1} \right) \quad (A.11)$$

In (A.9)-(A.11),  $N_{lk}$  is the number of lake nodes that make up a single lake and  $A_{lk}$  is the total surface area of a lake.

$$\diamond \quad \mathbb{X}_{i,i}^k = \left( \frac{\partial \mathbb{F}_i}{\partial \mathbb{H}_i^{t+1}} \right)^k = \frac{1}{\Delta t} \left( \frac{\partial S_{lk} \left[ \mathbb{H}_i^{t+1} \right]}{\partial \mathbb{H}_i^{t+1}} \right)^k + \sum_{j=1}^{N_{lk}} \left( \frac{\partial Q_{lkintj}^{t+1}}{\partial \mathbb{H}_i^{t+1}} \right)^k \quad (A.12)$$

where

$$\left( \frac{\partial S_{lk} \left[ \mathbb{H}_i^{t+1} \right]}{\partial \mathbb{H}_i^{t+1}} \right)^k = \sum_{j=1}^{N_{lk}} H \left[ \left( \mathbb{H}_i^{t+1} \right)^k - h_{blkj} \right] A_{lkj} \quad (A.13)$$

$$\left( \frac{\partial Q_{\text{lkint}j}^{t+1}}{\partial \mathbb{H}_i^{t+1}} \right)^k = \begin{cases} C_{\text{lk}j} & \text{if } (\mathbb{H}_i^{t+1})^k \geq h_{\text{blk}j} \\ 0 & \text{if } (\mathbb{H}_i^{t+1})^k < h_{\text{blk}j} \end{cases} \quad (\text{A.14})$$

and  $H[\bullet]$  is the Heaviside function.

$$\diamond \quad \mathbb{X}_{i,n}^k = \left( \frac{\partial \mathbb{F}_i}{\partial \mathbb{H}_n^{t+1}} \right)^k = \left( \frac{\partial Q_{\text{lkint}j}^{t+1}}{\partial \mathbb{H}_n^{t+1}} \right)^k = \begin{cases} -C_{\text{lk}j} & \text{if } (\mathbb{H}_n^{t+1})^k \geq h_{\text{blk}j} \\ 0 & \text{if } (\mathbb{H}_n^{t+1})^k < h_{\text{blk}j} \end{cases} \quad (\text{A.15})$$

where  $\mathbb{H}_n$  is the groundwater head at finite element node  $n$  that corresponds to lake node  $j$ .

### A.3. Components of $\{\mathbb{F}^k\}$ and $[\mathbb{X}^k]$ for Groundwater Nodes

For  $i = NR + NLK + 1, \dots, NR + NLK + N_L \cdot N$ :

$$\begin{aligned}
 \diamond \quad \mathbb{F}_i^k &= \frac{S_{S_i}^{t+1} A_i \left( \left( \mathbb{H}_i^{t+1} \right)^k - TOP_i \right) + S_{S_i}^t A_i \left( TOP_i - \mathbb{H}_i^t \right)}{\Delta t} \\
 &\quad - \sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} \iint_{\Gamma^e} q_{\Gamma^e}^{t+1} \omega_i^e d\Gamma^e \\
 &\quad - \sum_{\substack{j=N \cdot (m-1)+1 \\ j \neq i}}^{N \cdot m} \left( AT_{i,j}^{t+1} \right)^k \left( \left( \mathbb{H}_i^{t+1} \right)^k - \left( \mathbb{H}_j^{t+1} \right)^k \right) \\
 &\quad + H(m-2) L_{i-N} \left( \left( \Delta \mathbb{H}_i^u \right)^{t+1} \right)^k A_i \\
 &\quad + [1 - H(m - N_L)] L_{i+N} \left( \left( \Delta \mathbb{H}_i^d \right)^{t+1} \right)^k A_i \\
 &\quad - q_{o_i}^{t+1} A_i + \left\{ \left( S_{S_i}' \right)^t \frac{\left( h_i^{t+1} - h_{c_i}^t \right)}{\Delta t} + S_{sc_i} b_{o_i}^t \frac{\left( h_{c_i}^t - h_i^t \right)}{\Delta t} \right\} A_i \\
 &\quad - Q_{sint_i}^{t+1} - Q_{lkint_i}^{t+1} - Q_{td_i}^{t+1} \tag{A.16}
 \end{aligned}$$

where

$$\left( AT_{i,j}^{t+1} \right)^k = \sum_{e=N_e \cdot (m-1)+1}^{N_e \cdot m} \left( \left( T^e \right)^{t+1} \right)^k \iint_{\Omega^e} \bar{\nabla} \omega_i^e \bar{\nabla} \omega_j^e d\Omega^e \tag{A.17}$$

$$Q_{\text{sint}_i}^{t+1} = C_{S_{ns}} \left\{ \max \left[ \left( \mathbb{H}_{ns}^{t+1} \right)^k, h_{b_{ns}} \right] - \max \left[ \left( \mathbb{H}_i^{t+1} \right)^k, h_{b_{ns}} \right] \right\} \quad (\text{A.18})$$

$$Q_{\text{lkint}_i}^{t+1} = C_{\text{lk}_{nlk}} \left\{ \max \left[ \mathbb{H}_{\text{lk}}^{t+1}, h_{\text{blk}_{nlk}} \right] - \max \left[ \mathbb{H}_i^{t+1}, h_{\text{blk}_{nlk}} \right] \right\} \quad (\text{A.19})$$

$$Q_{\text{td}_i}^{t+1} = C_{\text{td}_i} \left( z_{\text{td}_i} - \mathbb{H}_i^{t+1} \right) \quad (\text{A.20})$$

In (A.16)-(A.20)  $ns$  is the stream node number that corresponds to groundwater node number  $i$  ( $1 \leq ns \leq \text{NR}$ ),  $lk$  is the lake number plus the total stream nodes ( $\text{NR} + 1 \leq lk \leq \text{NR} + \text{NLK}$ ), and  $nlk$  is the lake node number that corresponds to groundwater node number  $i$ .

$$\begin{aligned} \diamond \quad \mathbb{X}_{i,i}^k &= \left( \frac{\partial \mathbb{F}_i}{\partial \mathbb{H}_i^{t+1}} \right)^k \\ &= \frac{S_{s_i}^{t+1} A_i}{\Delta t} - \sum_{\substack{j=\text{N} \cdot (\text{m}-1)+1 \\ j \neq i}}^{\text{N} \cdot \text{m}} \left( A_{T_{i,j}^{t+1}} \right)^k \\ &\quad + H(\text{m}-2) L_{i-\text{N}} A_i \left( \frac{\partial \left( \Delta \mathbb{H}_i^u \right)^{t+1}}{\partial \mathbb{H}_i^{t+1}} \right)^k \\ &\quad + [1 - H(\text{m} - \text{N}_L)] L_{i+\text{N}} A_i \left( \frac{\partial \left( \Delta \mathbb{H}_i^d \right)^{t+1}}{\partial \mathbb{H}_i^{t+1}} \right)^k \\ &\quad + \frac{\left( S'_{s_i} \right)^t A_i}{\Delta t} - \left( \frac{\partial Q_{\text{sint}_i}^{t+1}}{\partial \mathbb{H}_i^{t+1}} \right)^k - \left( \frac{\partial Q_{\text{lkint}_i}^{t+1}}{\partial \mathbb{H}_i^{t+1}} \right)^k - \left( \frac{\partial Q_{\text{td}_i}^{t+1}}{\partial \mathbb{H}_i^{t+1}} \right)^k \end{aligned} \quad (\text{A.21})$$

where

$$\left( \frac{\partial (\Delta \mathbb{H}_i^u)^{t+1}}{\partial \mathbb{H}_i^{t+1}} \right)^k = \begin{cases} 1 & \text{if } \mathbb{H}_i^t \geq z_{b_i} \text{ (or } z_{k_i} \text{ if no aquitard is present)} \\ 0 & \text{if } \mathbb{H}_i^t < z_{b_i} \text{ (or } z_{k_i} \text{ if no aquitard is present)} \end{cases} \quad (\text{A.22})$$

$$\left( \frac{\partial (\Delta \mathbb{H}_i^d)^{t+1}}{\partial \mathbb{H}_i^{t+1}} \right)^k = \begin{cases} 1 & \text{if } \mathbb{H}_i^t \geq z_{t_i} \text{ (or } z_{k_i} \text{ if no aquitard is present)} \\ 0 & \text{if } \mathbb{H}_i^t < z_{t_i} \text{ (or } z_{k_i} \text{ if no aquitard is present)} \end{cases} \quad (\text{A.23})$$

$$\left( \frac{\partial Q_{\text{sint}_i}^{t+1}}{\partial \mathbb{H}_i^{t+1}} \right)^k = \begin{cases} -C_{s_{ns}} & \text{if } (\mathbb{H}_i^{t+1})^k > h_{b_{ns}} \\ 0 & \text{if } (\mathbb{H}_i^{t+1})^k \leq h_{b_{ns}} \end{cases} \quad (\text{A.24})$$

$$\left( \frac{\partial Q_{\text{lkint}_i}^{t+1}}{\partial \mathbb{H}_i^{t+1}} \right)^k = \begin{cases} -C_{\text{lk}_{nlk}} & \text{if } (\mathbb{H}_i^{t+1})^k > h_{\text{blk}_{nlk}} \\ 0 & \text{if } (\mathbb{H}_i^{t+1})^k \leq h_{\text{blk}_{nlk}} \end{cases} \quad (\text{A.25})$$

$$\left( \frac{\partial Q_{\text{td}_i}^{t+1}}{\partial \mathbb{H}_i^{t+1}} \right)^k = -C_{\text{td}_i} \quad (\text{A.26})$$

$$\diamond \quad \mathbb{X}_{i,i-N}^k = \left( \frac{\partial \mathbb{F}_i}{\partial \mathbb{H}_{i-N}^{t+1}} \right)^k = H(m-2) L_{i-N} A_i \left( \frac{\partial (\Delta \mathbb{H}_i^u)^{t+1}}{\partial \mathbb{H}_{i-N}^{t+1}} \right)^k \quad (\text{A.27})$$

where

$$\left( \frac{\partial (\Delta \mathbb{H}_i^u)^{t+1}}{\partial \mathbb{H}_{i-N}^{t+1}} \right)^k = \begin{cases} -1 & \text{if } \mathbb{H}_{i-N}^t > z_{t_i} \text{ (or } z_{k_i} \text{ if no aquitard is present)} \\ 0 & \text{if } \mathbb{H}_{i-N}^t \leq z_{t_i} \text{ (or } z_{k_i} \text{ if no aquitard is present)} \end{cases} \quad (\text{A.28})$$

$$\diamond \quad \mathbb{X}_{i,i+N}^k = \left( \frac{\partial \mathbb{F}_i}{\partial \mathbb{H}_{i+N}^{t+1}} \right)^k = [1 - H(m - N_L)] L_{i+N} A_i \left( \frac{\partial (\Delta \mathbb{H}_i^d)^{t+1}}{\partial \mathbb{H}_{i+N}^{t+1}} \right)^k \quad (\text{A.29})$$

where

$$\left( \frac{\partial (\Delta \mathbb{H}_i^d)^{t+1}}{\partial \mathbb{H}_{i+N}^{t+1}} \right)^k = \begin{cases} -1 & \text{if } \mathbb{H}_{i+N}^t > z_{b_i} \text{ (or } z_{k_i} \text{ if no aquitard is present)} \\ 0 & \text{if } \mathbb{H}_{i+N}^t \leq z_{b_i} \text{ (or } z_{k_i} \text{ if no aquitard is present)} \end{cases} \quad (\text{A.30})$$

$$\diamond \quad \mathbb{X}_{i,j}^k = \left( \frac{\partial \mathbb{F}_i}{\partial \mathbb{H}_j^{t+1}} \right)^k = (\mathbb{A} T_{i,j}^{t+1})^k \quad (\text{A.31})$$

$$\diamond \quad \mathbb{X}_{i,ns}^k = \left( \frac{\partial \mathbb{F}_i}{\partial \mathbb{H}_{ns}^{t+1}} \right)^k = \begin{cases} C_{s_{ns}} & \text{if } (\mathbb{H}_{ns}^{t+1})^k \geq h_{b_{ns}} \\ 0 & \text{if } (\mathbb{H}_{ns}^{t+1})^k < h_{b_{ns}} \end{cases} \quad (\text{A.32})$$

$$\diamond \quad \mathbb{X}_{i,lk}^k = \left( \frac{\partial \mathbb{F}_i}{\partial \mathbb{H}_{lk}^{t+1}} \right)^k = \begin{cases} C_{lk_{nlk}} & \text{if } (\mathbb{H}_{lk}^{t+1})^k \geq h_{b_{lk_{nlk}}} \\ 0 & \text{if } (\mathbb{H}_{lk}^{t+1})^k < h_{b_{lk_{nlk}}} \end{cases} \quad (\text{A.33})$$

## **Appendix B - Chronology of the Development of IGSM, IGSM2, and IWFM**

The roots of the IGSM code date back to an earlier code called FEGW2, developed by Dr. Young Yoon at UCLA in 1976. The first version of IGSM was also developed by Dr. Yoon (and his consulting staff) in 1990 as part of a contract funded by the Bureau of Reclamation Mid Pacific Region (MP), California Department of Water Resources (DWR), State Water Resources Control Board (SWRCB), and Contra Costa Water District (CCWD) (James M. Montgomery Consul. Eng. Inc., 1990).

Over the years, IGSM has undergone various upgrades by different groups based on specific applications to numerous basins in the United States (Table B.1); the model has been applied to groundwater basins in California, Colorado, and Florida. Applications of IGSM in California include the Central Valley, Sacramento County, Pajaro Valley, Friant Service Area, Alameda County, City of Sacramento, Pomona Valley, Salinas Valley, and the Chino Basin (Montgomery Watson, 1993).

No formalized version numbering system for IGSM was created until IGSM Version 3.0 in 1996. As a result, IGSM codes were not referenced in terms of a version number prior to 1996 (WRIME, 2000).

Thereafter, two separate groups developed IGSM versions 3.1 and 4.0 for application in the CVPIA-PEIS and Salinas Valley projects, respectively. However, not all the features developed for version 3.1 were included in version 4.0. The development of IGSM 5.0 in 2000 was an effort to consolidate all the features from both version 3.1 and 4.18 into a one comprehensive and upgraded IGSM version (Technical Memorandum

IGSM 5.0, 2000). Around that time, an IGSM User's Group was developed to discuss and share input, recommendations, and experiences of the IGSM users in the water community. Following the Peer Review process of IGSM conducted by the California Water and Environmental Modeling Forum, CWEMF (previously known as the Bay-Delta Modeling Forum, BDMF), the members of the IGSM Users Group strongly urged DWR to take the lead in overseeing the future development and technical support of IGSM. DWR has a strong interest in IGSM because of the use of the application of IGSM to the Central Valley in California CVGSM (Central Valley Groundwater and Surface water Model) in supporting the hydrology development and groundwater simulation in the CVP/SWP simulation model CalSim (previously known as DWRSIM).

DWR initiated a comprehensive review of the IGSM version 5.0 theories and code in January 2001. Following extensive revisions and enhancements to the theoretical basis of many of the processes simulated in IGSM and to the FORTRAN codes, it was decided to call the newly developed model IGSM2. The basic acronym was retained since to the end user many of the features between IGSM and IGSM2 were very similar. IGSM2 Version 1.0 was made available to the public in December 2002. Effective September 2005, IWFM was the new name for IGSM2. IWFM Version 2.4 was released in May 2006, Version 3.0 was released in February 2007 and Version 3.02 was released in April 2010.

<b>Version</b>	<b>Date</b>	<b>Model Features</b>	<b>Application Area</b>	<b>Model Co-Authors</b>
IGSM--	1976	New groundwater model	--	Young Yoon (UCLA)
IGSM--	1979	Major revisions to 1976 version	Basin Wide	Young Yoon Tetra Tech, Inc.
IGSM--	1979-1983	Enhancements	--	Young Yoon Boyle Engineering
IGSM--	1987	Stream routing	Central Valley	Young Yoon Boyle Engineering
IGSM 1.0	1990	Surface water and land surface processes, groundwater simulation	Central Valley and Other Applications	Young Yoon, Saquib Najmus, Ali Toghavi
IGSM 2.0	1994	Water quality simulation	Pajaro Valley Chino Basin	Young Yoon, Saquib Najmus
IGSM 2.1	1995	Reservoir operations	Salinas Valley	Young Yoon, Saquib Najmus, Ali Toghavi
IGSM 2.2	1995	Vadose zone, water quality improvements, land use	Chino Basin	Saquib Najmus
IGSM 2.3	1996	Regional scale tile drain simulation	Imperial County	Ali Toghavi
IGSM 3.0	1996	Multi-model integration	ARWRI	Young Yoon
IGSM 3.1	1997	Land subsidence	CVPIA-PEIS	Ali Toghavi
IGSM 4.0	1997	English and SI units	--	Ali Toghavi
IGSM 4.10-4.18	1998-1999	Reservoir operations improvements, crop water use	Salinas Valley	Ali Toghavi
IGSM 5.0	2000	Consolidation of all previous versions of IGSM	DWR-ISI	Ali Toghavi Saquib Najmus

**Table B.1** Chronological development of IGSM (up to version 5.0), IGSM2 and IWFM

<b>Version</b>	<b>Date</b>	<b>Model Features</b>	<b>Application Area</b>	<b>Model Co-Authors</b>
IGSM2 1.0	2002	Major revisions to IGSM 5.0 theories and code	--	Emin Can Dogrul
IGSM2 1.01	2003	Minor corrections	--	Emin Can Dogrul
IGSM2 2.0	2003	More robust solution techniques, improved simulation of aquifer-surface water interactions and output files	--	Emin Can Dogrul
IGSM2 2.01	2004	Minor corrections	--	Emin Can Dogrul
IGSM2 2.2	2005	Zone budgeting post-processor	--	Emin Can Dogrul
IWFM 2.3	2005	Re-use of irrigation return flow	--	Emin Can Dogrul
IWFM 2.4	2006	Modified routing procedure for root zone moisture	Butte County	Emin Can Dogrul
IWFM 3.0	2007	Enhancements in root zone moisture simulation, improved print-out features	Central Valley, Walla Walla Basin-OR	Emin Can Dogrul
IWFM 3.02	2010	Efficient generalized preconditioned conjugate gradient solver, modifications for faster run-times, bug fixes	Central Valley	Emin Can Dogrul
