Director
Department of Water Resources

Foreword

The Department of Water Resources is issuing this report to assist the contractors of the State Water Project in the assessment of the adequacy of the SWP component of their overall water supplies. SWP delivery reliability is of direct interest to them and those they serve because it is an important element of their overall water supply.

Local supply reliability is of key importance to local planners and government officials who have the responsibility to plan for future growth while assuring an adequate and affordable water supply is available for the existing population and businesses. This function is usually conducted in the course of preparing a water management plan such as the Urban Water Management Plans required by Water Code Section 10610. Information in this report may be used by local agencies in preparing or amending their water management plans and identifying the new facilities or programs that may be necessary to meet future water needs.

Local agencies will also find this report useful in conducting analyses mandated by legislation authored by Senator Sheila Kuehl (SB 221) and Senator Jim Costa (SB 610). These laws require water retailers to demonstrate the sufficiency of their water supplies for certain proposed subdivisions and development projects subject to the California Environmental Quality Act.

The Department is available to assist local agencies in the development of Urban Water Management Plans, the development of water conservation programs, and in applying the information contained in this report to specific water users. In addition, DWR has published a draft guidebook on how cities and counties can comply with Senate Bills 221 and 610.

The SWP Delivery Reliability Report was issued as a draft in August 2002. Public review of the draft consisted of six meetings throughout the state to explain the report and discuss the related issues and concerns, and the receipt of written comments through October 2002. This final report incorporates the comments and concerns of the public. Copies of all comment letters and their associated responses are included as Appendix E. We will continue to involve the public in discussion of the information contained in this report and in evaluation of the sufficiency of the analytical tool, CALSIM II, for developing this information.

For additional information or questions about this report please contact the Department's Bay-Delta Office at (916) 653-1099.

The State Water Project Delivery Reliability Report

Preface

Will there be enough water? Public officials throughout California face this question with increasing frequency as growth and competing uses strain existing resources. Water supply, however, has always been an uncertain and contentious matter in our State. For many years, the Department of Water Resources (DWR) has investigated this question. At its simplest level, the question might be, “How many wells are needed for a rural town’s water supply?” or “How many people can a 100,000 acre-foot reservoir serve?” But for most areas of the State, the evaluation of water supply adequacy is not simple. The answer requires a complex analysis, taking into account multiple sources of water, a range of uses, the timing of use, hydrology, available facilities, regulatory restraints, and, of course, future weather patterns. Most water users in California live in areas with multiple sources of water. Typically, local water providers “mix and match” these sources to maximize water supply and quality and to minimize cost. The answer to the question of water supply adequacy must take into account this mix-and-match practice and incorporate information about all water sources and their interrelation.

Much of the Department’s work in investigating the State’s water supply has focused on the State Water Project. The SWP supplies two-thirds of the State’s population with a portion of its water supply and provides water to irrigate, in part, 600,000 acres of agriculture. This report presents DWR’s current information regarding the annual water delivery reliability of the SWP. The report does not analyze how specific local water agencies integrate SWP water into their water supply equation. That topic requires extensive information about local facilities, local water resources, and local water use, which is beyond the scope of this report. Moreover, such an analysis would require decisions about water supply and use that traditionally have been made at

the local level. The Department believes it is appropriate that local officials continue to fill this role. This report does provide examples under various scenarios that explain how the SWP supply can be integrated into local water management.

Public Review

A draft of this report was released in late August 2002. Six public meetings were held throughout the State in October 2002 to explain the report and discuss related issues and concerns. Written comments were accepted through the end of that month. This final report incorporates the comments and concerns of the public. Copies of all comment letters and their associated responses are included in Appendix E.

This report is being sent to city, county, local and regional planning agencies within the SWP service area. It is also posted on the Web at <http://swpdelivery.water.ca.gov>. The Department will update this report every two years or more frequently should study factors change significantly or if improvement in the analytical tools warrants an earlier release.

Purpose

This report provides current information on the ability of the SWP to deliver water under existing and future levels of development, assuming historical patterns of precipitation. The SWP delivers water under long-term contracts to 29 public water agencies throughout the State. They, in turn, either deliver water to water wholesalers or retailers or deliver it directly to agricultural and urban water users. This report first looks at the general subject of water delivery reliability, discusses how it is determined by the Department for the SWP, and provides estimates of SWP delivery reliability today and in the future. It then discusses

Senate Bill 221

This law amends Section 11010 of the Business and Professions Code and Section 65867.5 of the Government Code. It also adds Sections 66455.3 and 66473.7 to the Government Code.

Under the Subdivision Map Act, a legislative body of a city or county is required to deny approval of a tentative map, or a parcel map for which a tentative map is not required, if it makes any of a number of findings. Under the Planning and Zoning Law, a city, county, or city and county may not approve a development agreement unless the legislative body finds that the agreement is consistent with the general plan and any applicable specific plan. [SB 221 prohibits] approval of a tentative map, or a parcel map for which a tentative map was not required, or a development

agreement for a subdivision of property of more than 500 dwelling units, except as specified, including the design of the subdivision or the type of improvement, unless the legislative body of a city or county or the designated advisory agency provides written verification from the applicable public water system that a sufficient water supply is available or, in addition, a specified finding is made by the local agency that sufficient water supplies are, or will be, available prior to completion of the project.

(From Legislative Counsel's Digest of Senate Bill No. 221, 2001-2002 session, filed with Secretary of State Oct. 9, 2001, Chapter 642:88-89)

An exception is made for the County of San Diego if the Governor's Office of Planning and Research determines certain conditions are met.

the role this reliability plays in the determination of overall water supply reliability for local water agencies.

The water delivery reliability of the SWP is of direct interest to those who use SWP supplies because it is an important element in the overall water supply in those areas. Local supply reliability is of key importance to local planners and local government officials who have the responsibility to plan for future growth while assuring that an adequate and affordable water supply is available for the existing population and businesses. This function is usually conducted in the course of preparing a water management plan such as the Urban Water Management Plans required by Water Code Section 10610. The information in this report may be used by local agencies in preparing or amending their water management plans and identifying the new facilities or programs that may be necessary to meet future water demands.

Local agencies also will find in this report information that is useful in conducting analyses mandated by legislation authored by Senator Sheila Kuehl (SB 221) and Senator Jim Costa (SB 610). These laws require water retailers to demonstrate whether their water supplies are sufficient for certain proposed subdivisions and development projects subject to the California Environmental Quality Act. The Department has published "Draft

Guidebook for Implementation of Senate Bill 610 and Senate Bill 221 of 2001," which includes suggestions on how local water suppliers can integrate supplies from other sources such as the SWP into their analyses. The draft guidebook can be found on the Web via the Department's Office of Water Use Efficiency home page, <http://www.owue.water.ca.gov>.

This delivery reliability report also responds to the recent criticisms of the Department in its administration of the SWP. Comments on the Monterey Amendment Environmental Impact Report stated that local planners and public officials were relying on inflated estimates of water supply from the SWP in approving new development. This report provides local officials with a single source of the most current data available on SWP delivery reliability for use in local planning decisions.

Senate Bill 610

This law amends Section 21151.9 of the Public Resources Code, and Sections 10631, 10656, 10910, 10911, 10912, and 10915 of the Water Code. It also repeals Section 10913 and adds and expires Section 10657 of the Water Code.

This [law requires] additional information be included as part of an urban water management plan if groundwater is identified as a source of water available to the supplier. [It] requires an urban water supplier to include in the plan a description of all water supply projects and programs that may be undertaken to meet total projected water use. [It prohibits] an urban water supplier that fails to prepare or submit the plan to the [California Department of Water Resources] from receiving funding made available from specified bond acts until the plan is submitted. The law, until January 1, 2006, requires the department to take into consideration whether the urban water supplier has submitted an updated plan, as specified, in determining eligibility for funds made available pursuant to any program administered by the department.

[In addition, the law] requires a city or county that determines a project is subject to the California Environmental Quality Act to identify any public water system that may supply water for the project and to request those public water systems to prepare a specified water supply assessment, except as otherwise specified. [It requires] the assessment include, among other information, an identification of existing water supply entitlements,

water rights, or water service contracts relevant to the identified water supply for the proposed project and water received in prior years pursuant to those entitlements, rights, and contracts. The [law requires] the city or county, if it is not able to identify any public water system that may supply water for the project, to prepare the water supply assessment after a prescribed consultation.

The [law prescribes] a timeframe within which a public water system is required to submit the assessment to the city or county and would authorize the city or county to seek a writ of mandamus to compel the public water system to comply with requirements relating to the submission of the assessment.

[It requires] the public water system, or the city or county, as applicable, if that entity concludes that water supplies are, or will be, insufficient, to submit the plans for acquiring additional water supplies. [It also requires] the city or county to include the water supply assessment and certain other information in any environmental document prepared for the project pursuant to the act.

(From Legislative Counsel's Digest of Senate Bill No. 610, 2001-2002 session, filed with Secretary of State Oct. 9, 2001, Chapter 643:94-95.)

An exception is made for the County of San Diego if the Governor's Office of Planning and Research determines certain conditions are met.

I

Water Delivery Reliability In General

What is Water Delivery Reliability?

“Water delivery reliability” means how much one can count on a certain amount of water being delivered to a specific place at a specific time.

Objectively, water delivery reliability indicates a particular amount of water that can be delivered with a certain numeric frequency. A delivery reliability analysis assesses such things as facilities, system operation, and weather projections.

Subjectively, water delivery reliability indicates an acceptable or desirable level of dependability of water deliveries to the people receiving the water. Usually, a local water agency in coordination with the public it serves determines the acceptable level of reliability and plans for new facilities, programs, or additional water supply sources to meet or maintain this level.

What Factors Determine Water Delivery Reliability?

In its simplest terms, water delivery reliability depends on three general factors:

- 1) Availability of water from the source (that is, the natural source or sources of the water from which the supplier draws—the particular watercourse or groundwater basin). Availability of water from the source depends on the amount and timing of precipitation and runoff, or “hydrology,” which provides water to the stream or groundwater basin, and the anticipated patterns of use and consumption of the source water by others, including water returned to the source after use.
- 2) Availability of means of conveyance (that is, the means for conveying the water from the source via pumps, diversion works, reservoirs, canals, etc. to its point of delivery). The ability to convey water from the source depends on the existence and physical capacity of the diversion, storage, and conveyance facilities and also

on any contractual, statutory, and regulatory limitations on the use of the facilities.

- 3) The level and pattern of water demand at the place of delivery. The level of demand for water at the place of delivery is defined by the magnitude of the demand, types of uses, local weather patterns, costs, and other factors. Supply from a water system may be sufficiently reliable at a low level of demand but may become less reliable as the demand increases. In other cases under increased demand, the water supply system may be able to deliver more water than in the past and maintain its reliability because use of the system’s facilities had not been maximized.

How is Water Delivery Reliability Determined?

Water Delivery Reliability is Defined for a Specific Point in Time

For this report, water delivery reliability is analyzed for 2001 conditions and for conditions projected to exist 20 years in the future (2021). These analyses must describe current conditions adequately and make predictions about the three factors described earlier.

The Availability of Water at the Source

This factor depends on how much rain and snow there will be in any given year and what the level of development (that is, the use of water) will be in the source areas. While no model or tool can predict what actual, natural water supplies will be for any year or years, and until we are able to evaluate climate change in California, future weather patterns will be assumed similar to those in the past, especially where there is a long historical rainfall record.

The SWP analyses contained in this report are based upon 73 years of historical records (1922-1994) for rainfall

and runoff that have been adjusted to reflect the current and future levels of development by analyzing land use patterns in the source areas and projecting future land and water use. These series of data are then used to forecast the amount of water available to the SWP under current and future conditions. (The series will be extended through 1998 in the near future.)

Recent studies on climate change conclude a warming trend exists that could change the long-term behavior of rainfall and snowmelt. Higher temperatures could have a large impact on natural runoff, especially in the lower elevation northern Sierra. If precipitation amounts are assumed to not change significantly, global warming would mean less snow forming in the lower elevations and less snowpack overall. These conditions would result in more direct rainfall runoff during the winter and less spring runoff due to snowmelt. Regional climate model studies by researchers at Scripps Institution of Oceanography indicate a reduction in snow water equivalent by about one-third to one-half current levels by the middle and end of the century, respectively. A recent model study released by UC Santa Cruz researchers that studied climate response to increases in atmospheric carbon dioxide concluded that Sierra snow accumulation would decrease everywhere and precipitation would increase in the northern regions by about 25 percent. Snowpack would also be gone by the end of April. Streamflow studies by researchers at Lawrence Berkeley National Laboratory for the Feather River show a shift to increased flows before March/April and lower flows the following months. The impact of this trend upon SWP water supply will be analyzed as more information becomes available. Global warming is being evaluated as part of the *California Water Plan Update 2003*. Information on *Update 2003* is available on the Department's Web site, www.waterplan.water.ca.gov.

The Ability to Convey Water from the Source to the Desired Point of Delivery

This factor describes the facilities available to capture and convey surface water or groundwater and the institutional limitations placed upon the facilities. The facilities and institutional limitations may be assumed to be those currently existing. Alternatively, predictions may be made regarding planned new facilities. Assumptions made about the institutional limitations to operation—such as legal, contractual, or regulatory restrictions—often are based upon existing conditions. Future changes in conditions that affect the ability to convey water usually cannot be predicted with certainty, particularly the regulatory and other institutional constraints on water conveyance.

Although new facilities are planned to increase the water delivery capability of the SWP, the analyses contained in this report assume no additional facilities in order to provide a conservative estimate of water delivery reliability. The analyses also assume current institutional limitations will exist 20 years in the future (2021).

The Level of Demand

This factor includes the amount and pattern of demand upon the water system. Demand can have a significant effect upon the reliability of a water system. For example, if the demand occurs only three months in the summer, a water system with a sufficient annual supply but insufficient water storage may not be able to reliably meet the demand. If, however, the same amount of demand is distributed over the year, the system could more easily meet the demand because the need for water storage is reduced.

Demand levels for the SWP are derived from historical data and information received from the SWP contractors. Demand on the SWP is nearing the full Table A amount. Each contractor has a Table A, which lists acre-feet amounts per year, usually increasing over time. Most contractors' Table A amounts reached the maximum in 1990. The total of all contractors' maximum Table A amounts is 4.173 million acre-feet (maf). Table A is used to define each contractor's proportion of the available water supply that the Department will allocate and deliver to that contractor. The Table A amounts in any particular contract, accordingly, should not be read as a guarantee of that amount but rather as the tool in an allocation process that defines an

individual contractor’s “slice of the pie.” The size of the “pie” itself is determined by the factors described in this report. (See Appendix C for additional explanation and listing of the maximum Table A amounts.)

There are 29 contractors of the SWP. Yuba City, Butte County, and Plumas County Flood Control and Water Conservation District are north of the Delta. Their maximum Table A amounts total 0.040 maf. The maximum Table A amounts for the remaining 26 contractors, which receive their supply from the Delta, total 4.133 maf. This report focuses on SWP deliveries from the Delta because the amount of water pumped from the Delta by SWP facilities is the most significant component of the total amount of SWP deliveries. The results presented in this report regarding the percent of Table A deliveries applies to Yuba City, Butte County, and Plumas County Flood Control and Water Conservation District in the same manner as the other contractors.

For year 2001, SWP demands from the Delta are estimated to vary from 3.0 to 4.1 maf per year depending upon the weather conditions in the demand areas. For the year 2021, the demand is estimated two ways. The first is to assume the demand depends upon weather conditions (study 2021A). This method is consistent with the one used for the 2001 study and produces a demand that varies from 3.3 to 4.1 maf per year. The increase in the value of the lower end of the range between the 2001 and 2021 levels is due to a projected increase in population and land development in the service areas. The value of the upper end of the range cannot rise above 4.1 maf because it is at the maximum Table A amount. The second estimation method is to assume that the contractors’ demands will be their maximum Table A amount, 4.1 maf per year, regardless of the weather in the demand areas (study 2021B). The results from this study provide information on the significance of the weather-variability assumption for 2021 and give an indication of the additional water supply that could be made available to the SWP contractors if places were available to store it.

Past Deliveries Cannot Accurately Predict Future Deliveries

It is worthwhile to note that actual, historical water deliveries cannot be used with a significant degree of certainty to predict what water deliveries will be. As discussed earlier, there are continual, significant changes over time in the determinants of water delivery: changes in water storage and delivery facilities, in water use by others, in water demand, and in the regulatory constraints on the use of facilities for the delivery of water. Given the very significant historical changes that have occurred, past deliveries are not necessarily good predictors of current deliveries, much less of future deliveries.

For example, the demand 30 years ago for water from the SWP was not as high as it is currently or expected to be in the future. Because the need for SWP water then was relatively low, less water was transported through the SWP during normal and wet times than could have been if the demand had been higher. Simply put, less water was delivered in those past years because less water was needed. Conversely, the current or projected delivery capability of a water project would be less than the past if (1) demand for water from a water project had been at its maximum level for many years, (2) no new facilities had been built, and (3) the supply from one of its main sources of water had recently been reduced because another entity with a prior water right increased its use of that source.

Many Assumptions Must Be Made in the Determination and Analysis of Water Delivery Reliability

As discussed earlier, to plan for the future, many assumptions must be made about the future. One of the most significant assumptions for water planning in general is how wet or dry the weather will be. For many planning purposes, the assumption is that future patterns of weather will be like the past, and an effort is made to develop information on the longest historical period for which acceptable records exist.

Using the historical record, planners analyze the worst drought in the period of record to evaluate how the water system will respond. Precipitation information for the Central Valley used for this report begins in 1922 and records the area’s worst drought from 1928 to 1934,

although the brief 1976 to 1977 drought was more acutely dry. Whatever assumptions are made, every responsible water delivery reliability analysis should expressly set forth the assumptions used in arriving at the number or numbers produced. It should always be understood that those numbers depend on, and are no better than, the assumptions upon which they must necessarily rest.

Because assumptions are the foundation upon which the estimates are made, people reviewing the estimates may wonder about the impact any particular assumption has upon the study results. For example, what impact would a significant increase in water use in the source areas have upon the projected SWP water delivery reliability? Would it significantly reduce the amount of SWP supply and, if so, by how much? These types of questions can be answered by varying specific factors to see the impact upon the results. These studies are referred to as sensitivity analyses and can be helpful in assessing the importance of certain assumptions to the study results. Sensitivity studies will be done in the near future on SWP water delivery analyses.

II

Determining Water Delivery Reliability

Study Assumptions

The selection of the assumptions and the factors that go into the determination of future water delivery reliability is very important and must be tailored to the particular water supplier. Assumptions and factors for the SWP concern, in particular, Sacramento and San Joaquin river basin precipitation; water rights and uses; SWP storage and conveyance facilities, including diversion facilities in the Delta; SWP service area demand; and the statutes, regulations, and contractual provisions that govern and regulate the SWP, including coordinating operations with the federal Central Valley Project. A detailed list of the study assumptions for this report are contained in Appendix A.

The assumptions for the studies for this report are the same across all studies except for two elements: the projected water use in the source areas and assumed SWP demands. Water use in the areas supplying water to the SWP (source areas) is represented at the current level of use in the 2001 study and at a level projected to occur

20 years in the future for the 2021 studies. The demand of the SWP contractors is at its current level for the 2001 study and is projected to increase to be very near or at the maximum level in the 2021 studies.

The 2021 studies differ in only one respect. In one study, the SWP demand varies each year with the weather in the delivery areas (2021A). In the other study, the SWP demand is maximized each year, regardless of weather (2021B). Table 1 summarizes these key assumptions. There are two types of deliveries assumed for the SWP contractors: Table A and Article 21. Article 21 deliveries are available on an unscheduled and interruptible basis and are not counted as part of the Table A amount. (See Page 13 for more discussion of Article 21.)

Selecting and quantifying the assumptions and factors comprise just the first step in the analysis. The next step involves fitting them together and describing or predicting how they interact to affect the ability of the SWP to make water deliveries.

Table 1—Key study assumptions

<i>Common assumptions</i>		
Existing facilities and operation requirements	Environmental Water Account included	
<i>Study-specific assumptions</i>		
<i>Study</i>	<i>Use of water in source areas</i>	<i>SWP contractors' demands from the Delta</i>
Study 2001	2001 level of development	Table A demand: 3.0-4.1 maf/yr, weather variable Article 21 demand: Up to 84 taf/mo
Study 2021A	2020 level of development ¹	Table A demand: 3.3-4.1 maf/yr, weather variable Article 21 demand: Up to 84 taf/mo, Apr-Nov Up to 134 taf/mo, Dec-Mar
Study 2021B	2020 level of development ¹	Table A demand: 4.1 maf/yr Article 21 demand: Same as Study 2021A

¹Assumed sufficient for 2021
taf = thousand acre-feet

Fitting the Assumptions and Factors Together: Models

The best tools available for fitting the assumptions and factors together to predict SWP water deliveries are the computer simulation models that DWR and the U.S. Bureau of Reclamation have developed over the years for their various water planning purposes. The most recent of these models is a combined State and federal model called CALSIM.

CALSIM simulates the operations of the SWP and Central Valley Project (CVP) under various assumed hydrologic conditions, regulations, and facility configurations to estimate water deliveries to SWP and CVP water users.

The Usefulness of the CALSIM Model

CALSIM and its predecessor models can be used in two ways. The first is in the comparative mode and the other is in the stand-alone mode. The comparative mode consists of comparing two model runs—one that contains a proposed action and one that does not. The proposed action could be the addition of a new reservoir or changes in operation regulations. Differences in certain factors, such as deliveries or reservoir storage levels, are analyzed to determine the effect of the proposed action. The model assumptions are less significant in a comparative study than a stand-alone study because all of the assumptions are the same for both the “with-action” and “without-action” model runs, except the action itself, and the focus of the analysis is the differences in the results.

In the stand-alone mode, the results of one model run, such as the amount of delivery or reservoir levels, are analyzed directly. The only information available to compare with the results is historical information that, for the reasons discussed earlier, is not directly comparable. The assumptions for a stand-alone study are, therefore, very significant. The SWP delivery reliability estimates use stand-alone computer model studies.

DWR is constantly working to improve the accuracy and usefulness of CALSIM, particularly the information and assumptions put into the model and the way in which that input is processed. Model study results and assumptions are critiqued by an interagency/stakeholder group and are available via DWR’s modeling Web site, <http://modeling.water.ca.gov/>. DWR’s models are also

reviewed and discussed at the California Water and Environmental Modeling Forum (formerly the Bay-Delta Modeling Forum), a statewide organization dedicated to increasing the usefulness of computer models for analyzing California’s water-related problems with emphasis in the Central Valley, Delta, and Bay. More information about the Modeling Forum is on its Web site, <http://www.cwemf.org/>.

Even though CALSIM provides a very comprehensive “picture” of the water delivery reliability of the SWP, it necessarily makes simplifying assumptions and relies on data input that is less than perfect. On the other hand, the complexity of assumptions and factors that must enter into any reasonable determination of delivery reliability must be considered and dealt with somehow. CALSIM is by far the best tool available for that purpose. The current version, CALSIM II, was used for the studies contained in this report.

Results of the studies contained in this report differ from results of studies using earlier versions of CALSIM. For example, the average water delivery reliability of the SWP estimated for study 2021A in this report is 75 percent of full Table A. An earlier study released by DWR estimated an average water delivery of 80 percent¹. One of the primary reasons for this difference relates to the method used to calculate the amount of flow from the Sacramento-San Joaquin Delta necessary to maintain the water quality standards of the Delta. The method used for this report calculates more outflow is needed to maintain Delta water quality, and, therefore, less water is available for SWP deliveries. The technical staff of DWR believes the new method more accurately estimates Delta outflow requirements. Staff has modified CALSIM accordingly. (See Appendix E for additional information.) Another reason for the difference is improvement of CALSIM’s hydrology. Technical staff from DWR and U.S. Bureau of Reclamation have worked together over the past year and have successfully developed hydrology that both agencies have approved. CALSIM II includes this improved hydrology.

DWR will continue to investigate how well CALSIM II simulates water operations and its sensitivity to the assumptions incorporated into the studies. This investigation is also important to the development of the *California*

¹ Model study 2020D09E-ISDP-964 conducted by the California Department of Water Resources.

Water Plan Update 2003 and the analysis of storage and conveyance projects proposed under the CALFED Program. Over the next year, DWR will conduct exercises in this regard. One exercise will analyze how well CALSIM II can simulate the water project deliveries for a recent historical period. The second exercise will be a series of studies of the changes in SWP deliveries produced by varying specific assumptions of the model's input. For example, the effect of a large increase in water use in the source areas upon SWP deliveries could be evaluated. Reports of the results of these exercises will be made available to the public when they are completed.

In addition, a peer review will be conducted by the CALFED Science Program to evaluate the adequacy of using CALSIM II to estimate SWP delivery reliability. Additional information on this review will be posted on the Web site—<http://swpdelivery.water.ca.gov>—for the *State Water Project Delivery Reliability Report*.

III

Study Results

The annual amounts of SWP deliveries estimated by CALSIM II are listed in tables B-3, B-4, and B-5 of Appendix B. This chapter contains tables summarizing the estimated delivery amounts for the entire study period, dry years, and wet years and presents information on the estimated probability of SWP delivery amounts.

Article 21 Deliveries

The studies estimate delivery amounts for Table A and Article 21. As mentioned earlier, Table A is the contractual method for allocating available supply, and the total of all maximum Table A amounts for deliveries from the Delta is 4.133 million acre-feet (maf) per year. Article 21 refers to a provision in the contract for delivering water that is available in addition to Table A amounts. (See Appendices C and D for more discussion.) Article 21 of SWP contracts allows contractors to receive additional water deliveries only under specific conditions. These conditions are:

- 1) It is available only when it does not interfere with SWP allocations;
- 2) It is available only when excess water is available in the Delta;
- 3) It is available only when conveyance capacity is not being used for SWP purposes or scheduled SWP deliveries; and
- 4) It cannot be stored within the SWP system. In other words, the contractors must be able to use the Article 21 water directly or store it in their own system.

Water supply under Article 21 becomes available only during wet months of the year, generally December through March. Because an SWP contractor must have an immediate use for Article 21 supply or a place to store it outside of the SWP, not all SWP contractors can take advantage of this additional supply.

Its importance to local water supply is tied to how each contractor uses its SWP supply. For those SWP contractors who are able to store their wet weather

supplies, Article 21 can be stored by being put directly into a reservoir or by offsetting other water that would have been withdrawn from storage, such as local groundwater. In the absence of storage, Article 21 water is not likely to contribute significantly to local water supply reliability. Incorporating supplies received under Article 21 into the assessment of water supply reliability is a local decision based on specific local circumstances, facts, and level of water supply reliability required.

This report presents information on Article 21 water separately so local agencies can choose whether it is appropriate to incorporate this supply in their analyses.

SWP Water Deliveries under Different Hydrologic Scenarios

The results of the studies estimating SWP water deliveries under current conditions (2001) and 2021 conditions are summarized in tables 2, 3, and 4.

Average, Maximum, and Minimum

Table 2 contains the average, maximum, and minimum values for studies 2001, 2021A, and 2021B. Comparing the results for 2001 and 2021A (weather variable demand) shows the average Table A delivery value is projected to increase by only 3+ percent points, from 72 percent to 75 percent over the next 20 years. When it is assumed the demand for 2021 will not vary with the weather and will be constant at 4.13 maf (2021B study), the average Table A delivery value is 76 percent, only 1 percent point above the 2021A study. These relatively small differences indicate that the SWP Table A demand is very near the full Table A amount. Recall that the delivery levels range from 3.0 maf per year to 4.1 maf per year for the 2001 study; from 3.3 maf per year to 4.1 maf per year for the 2021A study; and is constant at 4.1 maf per year for the 2021B study.

Notice the average amount of water supply per year under Article 21 decreases from 130 thousand acre-feet

Table 2—SWP Table A and Article 21 deliveries from the Delta

<i>Study</i>	<i>Average</i>	<i>Maximum</i>	<i>Minimum</i>
<i>2001 study</i>			
Table A	2,960 taf (72%)	3,850 taf (93%)	800 taf (19%)
Article 21	130 taf	510 taf	0
<i>2021A study</i>			
Table A	3,080 (75%)	4,130 taf (100%)	830 taf (20%)
Article 21	80 taf	400 taf	0
<i>2021B study</i>			
Table A	3,130 (76%)	4,130 taf (100%)	830 taf (20%)
Article 21	70 taf	400 taf	0

Percent of Table A in parentheses.
Full Delta Table A = 4.133 maf per year.

Table 3—SWP Delta average and dry-year Table A deliveries (in percent of full Table A)

<i>Study</i>	<i>Average 1922-1994</i>	<i>Single dry year 1977</i>	<i>2-year drought 1976-1977</i>	<i>4-year drought 1931-1934</i>	<i>6-year drought 1987-1992</i>	<i>6-year drought 1929-1934</i>
2001	72	19	48	37	41	40
2006	73	19	47	38	41	40
2011	74	20	46	38	41	41
2016	74	20	45	39	40	41
2021	75	20	44	39	40	41

Full Delta Table A = 4.133 maf per year.

(taf) in study 2001 to 80 taf in study 2021A. Water pumped from the Delta will go toward meeting Table A demands prior to being made available under Article 21. The 50 taf decrease is a direct result of the assumed increase in Table A demand for the 2021A study. Study 2021B reflects this same relationship with an average Article 21 delivery of 70 taf, slightly less than study 2021A.

Drought Years

Table 3 includes estimates of water deliveries under an assumed repetition of historical drought periods. The years are identified as dry by the Eight River Index, a good indicator of the relative amount of water supply available to the SWP. The Eight River Index is the sum of the unimpaired runoff from the four rivers in the Sacramento Basin used to define water conditions in the basin plus the four rivers in the San Joaquin Basin, which correspondingly

define water conditions in that basin. The eight rivers are the Sacramento, Feather, Yuba, American, Stanislaus, Tuolumne, Merced, and San Joaquin. Table 3 also includes the average deliveries for comparison purposes. These values are shown for 5-year intervals as required by SB 610. The intermediate estimates are simply linearly interpolated from the study results for 2001 and 2021. The results for the two studies for 2021 are essentially the same for these drought periods.

Even though the demands are projected to increase from 2001 to 2021 and the resulting amount of reservoir carryover storage is less, the drought deliveries are estimated to remain about the same (see Table 3). This result is attributable to the operation rules governing the amount of water that must be retained for carryover storage, the fact that SWP demand between 2001 and 2021

Table 4—Average and dry-year delivery under Article 21 (taf per year; year of delivery in parentheses)

Full Delta Table A = 4.133 maf per year.

increases relatively slightly, and because less water is made available under Article 21.

Table 4 summarizes the estimates of deliveries under Article 21. Notice the reductions for study year 2021 for the 2-year, 4-year, and 6-year droughts. This reduction is due to the increase in Table A deliveries.

Wet Years

The following two tables summarize the model run results for historical wet years. As with drought years, the Eight River Index is used to identify the wet years.

Table 5 illustrates the effect of the demand assumption upon Table A deliveries. The SWP demand assumed in the 2001 study is less than the projected demand of the 2021A

study; and the projected demand of the 2021A study is less than the 2021B study. Because plenty of water is available for deliveries, the lower the demand, the lower the Table A delivery amounts. The single wettest year (1983) provides a good example. In 1983, the Table A deliveries in study 2021A, which assumes a weather-variable demand, are estimated to be 9 percentage points greater than the study for 2001 (82 percent vs. 73 percent). Study 2021B, which assumes a higher demand (non-variable maximum demand), results in 100 percent of Table A delivery for the same year. This relationship is repeated for each wet period.

Historically, the level of demand under wet conditions in the Central Valley and Southern California is usually

**Table 6—Average and wet-year deliveries under Article 21
(taf per year; year of delivery in parentheses)**

						0 (1987)

Numbers rounded to the nearest 10,000 acre-feet.

lower than under dry conditions. This is because irrigation and landscape demand in the local area is being met by rainfall and local runoff is helping to fill local storage facilities. Study 2021A estimates Table A deliveries when SWP service area demand varies with the weather. The historical weather-variable pattern may change as additional storage is developed in local areas (such as Diamond Valley reservoir in Southern California). The results of study

2021B can be helpful to water district and agency planners in estimating the additional supply available under Table A if additional local facilities were built to store the water.

As a final note on Table 5, the average amount of annual Table A deliveries estimated under study 2021B decrease as the wet period lengthens. This is because the projected demands in study 2021B are fixed at 4.133 maf per year and the average amount of water available per year

to the SWP is less in the longer wet periods than the shorter ones. This pattern is not exhibited as well in study 2021A or at all in study 2001 because the annual demands are assumed to be lower during wet years.

Table 6 contains information about Article 21 deliveries for the same wet-year periods. The information illustrates a significant decrease in the availability of Article 21 supply between 2001 and 2021. This is primarily due to the increase in Table A demand.

SWP Table A Delivery Probability

The probability that a given level of SWP Table A amount will be delivered from the Delta is shown for the three studies in Figure 1. The plot lines in the figure are derived from the study results listed in tables B-3, B-4, and B-5 in Appendix B. Each line is constructed by ranking the 73 annual Table A delivery values of the relevant study from lowest to highest and calculating the percentage of values equal to or greater than the delivery value of interest. For example, for the 2021 studies, the value of 3.43 maf is in the

middle of the ranking; therefore, it is equaled or exceeded by half of the 73 delivery values. The delivery value of 0.83 maf, the minimum value for the 2021 studies, is equaled or exceeded by all of the delivery values. The curves have been smoothed to slightly assist with their analysis.

The curves for the 2021 studies are very similar for the lower portion of the ranking (that is, delivery values equaled or exceeded by 50 percent to 100 percent of the values). These lower values are similar because deliveries are limited by the amount of water available to the SWP for export from the Delta. The curve for the 2001 study shows the same characteristic with slight variation. The curves diverge within the upper range of the delivery values.

A comparison of the upper range of the studies for 2021 illustrates the effect the projected demand has upon SWP deliveries. The deliveries in study 2021B reach 100 percent more frequently than in study 2021A (weather-variable demand) because the demand for 100 percent of Table A deliveries is assumed for each year of study 2021B.

* Annual delivery rounded to nearest 10,000 acre-feet

Figure 1—SWP Delta delivery probability (Table A)

Figure 2—SWP contractors’ Table A request vs. 2001 model study SWP Table A demand

In study 2021A, the demand for 100 percent of Table A occurs in significantly fewer years and is rarely met because when 100 percent is assumed to be needed, the water year often cannot provide it. The delivery values in study 2001 never reach 100 percent Table A for the same reason.

The amount of SWP Table A delivery per year, either in percent of full Table A or in thousand acre-feet, associated with a specific degree of reliability can be determined from Figure 1. By referencing the curve for study 2021A or 2021B, the following can be deduced:

- In 75 percent of the years, the annual water delivery of the SWP is estimated to be at or above 2.70 maf per year (66 percent of 4.13 maf);
- In 50 percent of the years, it is estimated to be at or above 3.40 maf per year (83 percent of 4.13 maf); and
- In 10 percent of the years, it is at or greater than 4.10 maf per year (98 percent of 4.13 maf).

Figure 1 depicts the estimated reliability for the total of SWP deliveries. This information can be directly applied to individual long-term water supply contracts for the SWP. For example, if a water agency has a full SWP Table A amount of 300 taf, it can expect to receive at least 200 taf

per year (66 percent of 300 taf) 75 percent of the time. The individual curves for studies 2001, 2021A, and 2021B are in Appendix B.

Comparing Study Results for Table A Deliveries with Actual SWP Deliveries

The estimated amounts presented in this report for Table A deliveries are higher than historical Table A deliveries. For example, the average Table A delivery in the 2001 study for the period when SWP deliveries to the San Joaquin Valley began (1968) through the last year simulated (1994) is 2.93 maf per year. The average of the actual deliveries during that time is 1.39 maf per year. The primary reason for the difference is the fact that the demands for project water by the SWP contractors are much higher than they were in the past.

SWP contractors’ requests for water have significantly increased in recent years (Figure 2). 2001 is the first year that requests for Table A deliveries exceeded 4.0 maf. Because the 2001 model study includes water demands that are significantly higher than historical levels, modeled water

deliveries will exceed historical deliveries when the water supply is available.

DWR has conducted a study comparing the 2001 study to historical conditions under a recent period when water supply is limited to see how well the results compare. The comparison covers the drought period 1987–1992. To make the results comparable, certain adjustments must be made. These adjustments include accounting for differences in the actual and simulated reservoir storages at the beginning and end of the study period and accounting for the fact that the Delta water quality requirements in place during this period did not require as much water to flow out of the Delta to the San Francisco Bay as the requirements currently in place.

Without these adjustments, the average delivery in the 2001 study for this period is 1.67 maf per year. The actual deliveries average 2.03 maf per year. With the above mentioned adjustments, the average of the 2001 study results for this period is 1.98 maf per year, 50,000 acre-feet per year lower than the historical average. Therefore, rather than over-estimating deliveries, this comparison indicates CALSIM II slightly under-estimates deliveries during periods when water supply is low. This is an important conclusion that should help improve general confidence in using CALSIM II as an analytical tool. Additional discussion of this analysis is in Appendix E, the response to Sen. Michael J. Machado, Attachment 1, “Comparison of Historical and CALSIM II Deliveries for 1987-1992” (refer to Appendix E index, Page E-1).

Additional Analysis of Tables B-3, B-4, and B-5 in Appendix B

Information on the average deliveries over the entire study period and specific wet and dry periods is helpful in analyzing the delivery reliability of a specific water system receiving a portion of its water supply from the SWP. The series of data contained in tables B-3, B-4, and B-5 are also very helpful in analyzing longer periods of time that contain not only dry periods but wetter periods, which can replenish local water supplies if there is a place to store the supply. Analysis of this information can help determine if a local agency has adequate storage for capturing these supplies or if more storage could be utilized in the local water system.

IV

The Reliability of Local Water Supplies

The real significance of SWP water delivery reliability is not to the SWP itself but to the agency that ultimately provides the SWP water to its municipal, industrial, and agricultural customers and to the city or county that makes the land-use decisions in which water supply is a matter of key concern. SWP water delivery reliability is most important as it affects the local provider's overall water supply reliability.

This report does not recommend a particular level of SWP water delivery reliability for any individual SWP water contractor. The degree of reliability of SWP water deliveries that a local water provider desires or needs depends on the particular facts and circumstances that pertain to that provider. For example, if periodic shortages can be tolerated, then a lesser degree of SWP reliability will be "reliable enough." If, on the other hand, water is needed every year, say for permanent crops like orchards and vineyards, and no replacement supply is available, higher SWP water delivery reliability will be desired.

Local water delivery reliability depends not only on SWP supplies but upon all sources of supply to the local provider. For example, the local provider may have access to local surface water and groundwater supplies, to reclaimed water, or to other sources of imported water, which have different levels of reliability. If so, the local provider will manage all sources of supply together, each with its individual degree of reliability, to enhance overall reliability. It is also at the local level that demand itself may be managed to meet supply through conservation, water use efficiency, drought response planning, and land-use planning decisions made by local jurisdictions.

Two examples of fictional agencies are provided in this chapter to help illustrate how the information provided in this report may assist local water supply planners. A third example shows how the information must be carefully analyzed to avoid misinterpretation.

Greenacres Irrigation District

Greenacres Irrigation District provides water to a farming area in the Central Valley. The demand for water for uses other than irrigation is negligible. The district has two sources of water—surface water from the SWP and up to 110 thousand acre-feet (taf) per year of groundwater pumped from district-owned wells. Most of the water demand is for perennial crops (orchards and grapevines). The remaining is for annual field crops such as tomatoes and corn. The district's contract with the SWP is for a maximum Table A amount of 300 taf.

The district's water system can convey the full Table A amount if it is available, but there is no ability to store any unused supply. The cost of pumping groundwater is higher per acre-foot than the SWP supply; therefore, the district will maximize its use of SWP water. The average annual demand for the district is 300 taf. The district must deliver 180 taf annually to assure none of the trees and vines are lost. If conditions were extremely dry, permanent crops would have priority for the limited water supply. District managers are interested in analyzing a range of possible water supplies to assess the impact upon the district.

One item of interest is the probability of the district receiving at least 180 taf from the SWP now and in the future. These probabilities can be derived by using Figure 3. Figure 3 is the same as Figure 1 except Greenacres Irrigation District Table A amount is shown on the left axis. The minimum target for SWP deliveries for the district is 180 taf per year, or 60 percent of its maximum Table A amount. Figure 3 provides the district's current probability of receiving at least 180 taf per year from the SWP. It shows the district has an 80 percent chance of receiving at least 60 percent of Table A in any given year under all three study scenarios.

Figure 3—Greenacres Irrigation District delivery probability (Table A)

The district would like a better chance of assuring its minimum needs will be met and will use groundwater to make up the difference. From Figure 3, it is determined that SWP Table A deliveries of about 30 percent can be made or exceeded 90 percent of the time. This indicates that 90 taf will need to come from groundwater to assure minimum needs (180 taf) are met. The district can meet this amount of groundwater need.

The district can deliver up to 110 taf of groundwater in a particularly dry year. To meet its minimum need of 180 taf, 70 taf would be required from the SWP. The probability of the SWP providing that amount of Table A delivery is 98 percent (Figure 3, value corresponding to 23 percent of maximum Table A).

Finally and to help with long-term planning, the district would like to estimate the average amount of annual groundwater pumping. Figures 1 or 3 cannot be used for this analysis. Figures 1 and 3 provide the amount, in percent of full Table A, that is exceeded 50 percent of the time (80 to 83 percent). This value is called the median value. The average value and median value are not the same. Table 2 (see Page 14) contains the average Table A values. The average Table A delivery is estimated to be

72 percent in 2001 and 75 percent in 2021. These values indicate the district will receive an average Table A delivery from the SWP of 220 taf per year in 2001 and 230 taf per year in 2021. Correspondingly, groundwater pumping will average 80 taf per year in 2001 and 70 taf per year in 2021.

More detailed analyses can be done using the information contained in tables B-3, B-4, and B-5 in Appendix B. For example, the district may wish to analyze the drought periods to determine whether the ground-water system will be able to meet the district’s water needs if these periods were repeated.

The analyses for Greenacres Irrigation District focus on the dry periods because the district has no ability to store water during wet periods. This is not the case in the following example.

Southcity Water Agency

Southcity Water Agency serves a major metropolitan area with many high-technology industries. The water agency has several sources of water including the SWP. Because of the high drinking-water demands and the needs of the local industries, the quality of its water supply is very important to the agency.

The quality of water from the SWP is much better than most other sources of supply, so Southcity maximizes its use of Table A deliveries. It also receives a portion of its supply as deliveries under Article 21 when they are available. The district is interested in how its supply under Article 21 is projected to change over time.

Table 2 contains the estimated values for Article 21 supplies. The average and maximum deliveries are projected to decrease over time, even though the demand for Article 21 water is projected to increase. This is due to the increase in demand for Table A amounts. The district's projected Article 21 demands are included in the estimated demand of 84 taf per month contained in 2001 computer study. The district's amount of the estimated Article 21 demand for 2001 is 20 taf per month, or about 24 percent.

Table 2 indicates the district's amount of Article 21 deliveries will decrease over the 20-year period. For example, the maximum Article 21 delivery for 2001 is 510 taf per year. In this study, the demand is 84 taf per month. Assuming the district can take all its delivery, the district would receive 24 percent of 510 taf, or 120 taf, that year.

In both of the 2021 studies, the maximum Article 21 delivery is 400 taf per year. The district's portion of the Article 21 demand has dropped, however, because an additional demand of 50 taf per month for December through March is assumed. Due to the increased demand under Table A, the amount of Article 21 deliveries are less and the period of time they are available is shortened. In the 2021 studies, it is reasonable to assume Article 21 deliveries occur only during the December through March period. The estimated demand for Article 21 deliveries during that period is 134 taf per month for the 2021 studies. The district's portion of the Article 21 delivery is reduced from 24 percent to 15 percent (20/134). Therefore, the maximum the district can expect to receive at the assumed level of demand for 2021 is 15 percent of 400 taf, or 60 taf.

This cursory analysis indicates that, with no changes in its operation for Article 21 supply, the district's opportunity to receive this supply is projected to decrease over time. Further analysis would be necessary to explore specific operational changes or additional facilities the district would consider to maintain or improve its ability to receive Article 21 water.

Small Pipe Irrigation District

Small Pipe Irrigation District's sole water provider is the SWP. Small Pipe ID's contract with the SWP is for 300 taf per year; however, the water system for the district can convey a maximum of only 150 taf per year. Because of the limitation in the ability to receive deliveries, the results presented in this report do not apply directly to the district.

For example, 150 taf per year is 50 percent of the maximum Table A amount in the district's contract. Table B-3 contains 73 annual estimates for Table A deliveries. Out of these 73 values, 59 are greater than 50 percent. The average Table A delivery to Small Pipe ID is calculated by replacing any value greater than 50 percent in the table with 50 percent, summing up the new list of values, and dividing by 73. For Small Pipe ID, the average delivery for 2001 is estimated to be 46 percent of its maximum Table A amount, not 72 percent as shown in Table B-3 or Table 2. In addition, the probability curves will be different for the district, as well as the maximum delivery amounts. An obvious example is that Small Pipe ID's maximum delivery will be 50 percent of full Table A, not the estimated values shown in Table 5.

This example is to alert readers to the potential for misinterpretation of the information contained in this report. Questions regarding the use of this information may be directed to the Department of Water Resources' Bay-Delta Office at (916) 653-1099.

Appendix B

Computer Simulation Models

A study to determine the supply reliability of the State Water Project is done using a computer program that simulates the operation of the SWP on a monthly basis over a 73-year historical record of rainfall and runoff (1922-1994). The simulation model integrates all the relevant water resource components and calculates key water management parameters, such as:

- the amount of water released from reservoirs in the Sacramento-San Joaquin valleys,
- the amount of water required to maintain Delta water quality standards,
- the amount of water to be pumped from the Delta by the SWP and the Central Valley Project (CVP), and
- the amount of water that can be delivered by each of these projects.

The information required to run the simulation is referred to as the “model input.” The most significant categories of input are:

- the physical description of the water system facilities (maximum pumping or release capacity, maximum reservoir storages, etc);
- institutional requirements (delivery contract requirements, Delta water quality standards, the operations agreement between the SWP and CVP, endangered species requirements, and other requirements of federal and State laws, etc);
- hydrology (river and stream flows adjusted for water use in the source areas); and
- the level of SWP water demand.

CALSIM II

CALSIM II is the current version of the computer simulation model used to determine SWP delivery reliability. All versions of CALSIM employ commercially available linear programming software as a solution device. The application of the software, Graphical User Interface, and

Input/Output devices is discussed in the documentation for CALSIM.¹

The Study Assumptions

The studies done for this report answer two questions.

- 1) “What is the current delivery reliability of the SWP?” and
- 2) “What would the SWP be able to deliver in the year 2021, if there were no new facilities or improvements to existing facilities, SWP water demand increased, and the institutional requirements existing today were in place?”

Depending upon a person’s expectation of what the future holds, this estimate of SWP delivery capability could be viewed as either too low or too high. The estimate could be viewed as too low because the Department is planning to have facilities in place by 2021 that will increase the reliability of the SWP. The estimate could be viewed as too high because the population of endangered Delta fish species could, for example, decline in the future and require the operation of the SWP to be more restricted than it is today.

Key Study Assumptions

The key study assumptions are listed in Table B-1. Additional discussion of these studies is on the DWR Modeling Branch’s Web site (<http://modeling.water.ca.gov/>).

The Results

The annual delivery amounts calculated by the supply reliability studies are contained in tables B-3 (2001) and B-4 and B-5 (2021A and 2021B, respectively) at the back of this appendix. The tables show the demand level in thousand acre-feet (taf), the amount of delivery from the Delta, and percent of full Table A calculated for each year of simulation for the current condition (2001) and 2021.

¹ CALSIM documentation may be obtained through the DWR Modeling Branch’s Web site: <http://modeling.water.ca.gov>.

Table B-1—Key assumptions used in calculating SWP water delivery reliability

	<i>Level of development in source areas</i>	<i>SWP facilities</i>	<i>Operation requirements</i>	<i>CALFED Environmental Water Account</i>	<i>SWP demand level from the Delta</i>
2001 Study	2001	Existing	1. SWP Banks export limit set at 6,680 cfs w/certain exceptions. 2. Delta water quality standards per 1995 Delta Water Quality Control Plan. 3. Operation coordinated with the CVP per the 1986 Coordinated Operations Agreement.	Included	3.0 - 4.1 maf, weather dependent
2001A Study	2020 ¹	Same	1. Same 2. Same 3. Same	Same	3.0 - 4.1 maf, weather dependent
2001B Study	2020 ¹	Same	1. Same 2. Same 3. Same	Same	4.1 maf every year

CVP = Central Valley Project
maf = million acre-feet
¹Assumed sufficient for 2021

Table B-2—SWP Delta average and dry-year Table A deliveries (percent of full Table A)

<i>Year study</i>	<i>Average 1922-1994</i>	<i>Single dry year 1977</i>	<i>2-year drought 1976-1977</i>	<i>4-year drought 1931-1934</i>	<i>6-year drought 1987-1992</i>	<i>6-year drought 1929-1934</i>
2001	72	19	48	37	41	40
2006	73	19	47	38	41	40
2011	74	20	46	38	41	41
2016	74	20	45	39	40	41
2021	75	20	44	39	40	41

Full Delta Table A is 4.133 maf.

These values must be interpreted within the confines of the assumptions upon which they are calculated. For example, for the year 1958, in the 2021A study, the annual delivery is calculated to be 3,910 taf or 95 percent of full Table A (see Table B-4). This result should be stated as follows:

“If the rainfall were the same as it was in 1958 but (1) the level of water use in the source area was increased to the level it would be in 2021; (2) SWP facilities and operation requirements were the same as they are today; and (3) SWP contractor demands were very near their full Table A level, the SWP would deliver approximately 3,910 taf or 95 percent of full Table A.”

Actually, the conditional statement associated with the result for any particular year is even more complicated than

this because the result is also dependent upon the rainfall that has occurred in previous years. For example, if the previous year (1957) were wet, runoff for 1958 for the same amount of rainfall would be more than if 1957 were dry. In addition, reservoir storage for the beginning of 1958 would vary depending upon the weather conditions in 1957. This linkage makes each year’s simulation dependent upon the previous year’s and, hence, links the entire historical series.

Table B-2 contains a summary of the delivery estimates for the SWP for important dry periods in history computed by the studies. The five-year incremental values are linearly interpolated between the 2001 and 2021A values. This information can be helpful in analyzing the delivery reliability of a specific water system that receives a portion of its water supply from the SWP. The series of data

BST_2001D10A-ANNBENCHMARK_1_1

Figure B-1—Study 2001 SWP Delta delivery reliability

contained in tables B-3, B-4, and B-5 (see back of appendix) are also helpful in analyzing longer periods of time that contain not only dry periods but wetter periods, which can replenish water supplies.

Finally, to help analyze the chance of receiving a given level of delivery in any particular year, a probability distribution curve is useful. It simply shows the percent of the years the annual delivery estimate is at or above a given value. The probability distribution curves for 2001 and 2021 are included as figures B-1 (2001) and B-2 and B-3 (2021A and 2021B, respectively). For example, for the 2021A study (Figure B-2), the curve indicates that in 75 percent of the years, the annual delivery reliability is estimated to be at or above 66 percent of full Table A amounts or 2.73 maf. Similarly, annual delivery reliability during 50 percent of the years is estimated to be at or above 83 percent of full Table A or 3.43 maf. The curve also shows that in 10 percent of the years, annual delivery reliability is estimated to be greater than or equal to 98

percent of full Table A or 4.05 maf. A similar analysis can be done for the current condition using Figure B-1.

Appendix C

SWP Table A

What is SWP Table A?

The contracts between the Department of Water Resources and the 29 State Water Project water contractors define the terms and conditions governing the water delivery and cost repayment for the SWP. Table A is an exhibit to these contracts. Comprehension of Table A is important in understanding the information in this report. To understand the table, it is necessary to understand how the contracts work.

All water-supply related costs of the SWP are paid by the contractors, and Table A serves as a basis for allocating some of the costs among the contractors. In addition, Table A plays a key role in the annual allocation of available supply among contractors. When the SWP was being planned, the amount of water projected to be available for delivery to the contractors was 4.2 million acre-feet (maf) per year. This was referred to as the minimum project yield, and it was recognized that in some years the project would be unable to deliver that amount and in other years project supply could exceed that amount. The 4.2 maf number was used as the basis for apportioning available supply to each contractor and as a factor in calculating each

contractor's share of the project's costs. This apportionment is accomplished by Table A in each contract. Table A lists by year and acre-feet the portion of the 4.2 maf deliverable to each contractor. Other contract provisions permit changes to an individual contractor's Table A under special circumstances. The total of the maximums in all the contracts now equals 4.173 maf.

A copy of the consolidated Table A from all the contracts follows this explanation. The amounts listed in Table A cannot be viewed as an indication of the SWP water delivery reliability, nor should these amounts be used to support an expectation that a certain amount of water will be delivered to a contractor in any particular time span. Table A is simply a tool for apportioning available supply and cost obligations under the contract. In this report, reference to "Table A amounts" means the amounts listed in Table A. Contractors also receive other classifications of water from the project, as distinguished from Table A (for example, Article 21 water, and turnback pool water). These other contract provisions are discussed in Appendix D.

The maximum Table A is not the Table A amount for 2001 in every contract. A few contractors have, for financial reasons and with the Department's approval, reduced the Table A amount in their contract for a specified time.

Appendix D

SWP Historical Deliveries (1967–2002)

SWP Contract Water Types

The SWP contracts define several classifications of water available for delivery to contractors under specific circumstances. All classifications are considered “project” water. Many contractors make frequent use of these additional water types to increase or decrease the amount available to them under Table A.

Table A Water

Each contract’s Table A is the amount in acre-feet that is used to determine the portion of available supply to be delivered to that contractor. Once that apportionment is made, the water delivered is further limited by monthly peaking rates (18 percent per month for agricultural contractors and 11 percent per month for urban contractors). Table A water is water delivered according to this apportionment methodology and is given first priority for delivery.

Article 21 Water

Article 21 of the contracts permits delivery of water excess to delivery of Table A and some other water types to those contractors requesting it. Contractors requesting Article 21 water may take delivery of water in excess of the monthly peaking rates that apply to Table A water. Article 21 water is apportioned to those contractors requesting it in the same proportion as their Table A.

Article 12(d)

When the State was unable to deliver any portion of a contractor’s annual delivery under Table A as a result of causes beyond the State’s control, contract provision Article 12(d) allowed the contractors to take the water later in the year or in succeeding years. As the Monterey amendment became effective (1995-1997), 12(d) water was deleted.

Article 14(b)

Contractors whose Table A deliveries were curtailed due to an unscheduled outage may under specified circumstances request later deliveries of the Table A water that was undeliverable. Factors that influence how much water can be delivered include operational constraints of project facilities, filling of SWP reservoirs, and Delta water quality requirements. Deliveries of water under Article 14(b) may result in a contractor receiving more than the Table A amount in a single year.

Turnback Pool Water

Contractors may choose to offer scheduled deliveries of Table A water to a pool, which is established in February and March. Other contractors may state a desire to receive this “turnback” pool water. Contributing contractors receive a reduction in charges and taking contractors pay extra.

Carryover Water

Pursuant to the long-term water supply contracts, DWR has offered contractors the opportunity to carry over a portion of their allocated water approved for delivery in the current year for delivery during the next year. The carryover program was designed to encourage the most effective and beneficial use of water and to avoid obligating the contractors to use or lose the water by December 31 of each year. The water supply contracts state the criteria of carrying over Table A water from one year to the next. Normally, carryover water is water that has been exported during the year, not delivered to the contractor during that year, and remains stored in the SWP share of San Luis Reservoir to be delivered during the following year.

Appendix E

Public Comment Letters and DWR Responses

Written comments from the public on the *Draft State Water Project Delivery Reliability Report* (August 2002) were accepted through October 2002. DWR reviewed the letters and made appropriate modifications to the report. These letters and their responses are contained in the printed version of this report and are posted on the Web at <http://swpdelivery.water.ca.gov/commentletters.htm>.
